PREFACE.

This is the third of the County Memoirs dealing especially with Water Supply, but it must not be forgotten that Mr. Whitaker, who has been a pioneer in the matter of recording details of well sinkings and borings, prepared for us a volume of the well sections near London.

Although this work is intended to act as a geological guide for the water-bearing strata of Lincolnshire, it has been deemed advisable to include records of all borings made in the county for whatever purpose, as they are all helpful with regard to the local thicknesses and characters of the strata.

In gathering together the records, those issued in the several Memoirs illustrating the Geological Survey Sheets have formed a substantial nucleus; for many of them we were indebted to Mr. Whitaker, while others were collected during the survey of the county by Messrs Reid, Strahan, Ussher, and Jukes-Browne.

When the present work was planned, Mr. Henry Preston, who had been consulted, generously placed his MSS.containing many records of wells and borings at our disposal, while Dr. H. F. Parsons, whose personal acquaintance with the northern part of the county led him to take particular interest in the volume, has given us much information, and, through his kind offices, the Local Government Board have supplied us with particulars of numerous analyses of waters. We are indebted to Dr. Alfred Ashby, Mr. James Baynes and Mr. Otto Hehner for permission to publish analyses made by them.

Mr. J. Stuart Bogg has sent us particulars of a recent boring at Benniworth, together with copies of analyses of Kimeridge Clay. We are likewise indebted to various engineers, wellsinkers, and others, whose names are mentioned in the text, for records of borings, given generally in return for information supplied at the Geological Survey Office. The records thus received have been annotated by Mr. H. B. Woodward, who has arranged all the other materials, and has written the introductory notes.

The records are published as they have been received, but every care has been taken to define the geological horizons as indicated by the terms used by well-sinkers. It should, however, be remembered that these terms are sometimes inaccurate, as, for instance, when "gravel" is used for broken rock, and "sandstone" for oolite. (See p. 58.)

7696. 500.-Wt. 20571. 12/04. Wy. & S. 2085r.

a 2

In order to illustrate the subject as fully as possible, Dr. H. R. Mill, whose services we were fortunately able to secure, has contributed a report on the rainfall.

Details of the levels of water in wells at different seasons, would have been of much interest and value, but observations on these matters do not come within the province of the Geological Survey, and it has not been possible to collect the information.

J. J. H. TEALL,

Director.

Geological Survey Office, 28, Jermyn Street, London. 23rd November, 1904.

THE WATER SUPPLY OF LINCOLNSHIRE

FROM UNDERGROUND SOURCES.

OUTLINE OF THE GEOLOGY AS FAR AS RELATES TO WATER-SUPPLY.

INTRODUCTION.

The geological formations known to occur in Lincolnshire range from the Carboniferous to the Chalk, and include also Pleistocene and Recent deposits.

The formations which occupy the surface are naturally divided into three great groups :---

(1) The Triassic, Liassic and Oolitic series, which extend through the western half of the county, overlie one another in regular sequence, with a gentle easterly inclination, and thus outcrop in successive belts from west to east, with a northerly and southerly strike.

(2) The Cretaceous rocks, which in the north-eastern portion of the county stretch obliquely across the outcrops of the higher Oolitic strata, with an inclination to the north-east and a general strike to north-west and south-east. They comprise a lower sandy and clayey division; and an upper division of Chalk, which forms the Wolds and overlaps the sandy and clayey beds in the northern part of the county.

(3) The Glacial Drifts and other superficial deposits, which occur as great sheets and outlying patches, resting irregularly on any of the older formations in various parts of the county, and entirely concealing them in the south-eastern part.

Strata older than any of those just mentioned have been proved in certain deep borings. These include the Carboniferous and Permian, but as they cannot be regarded as sources of water supply, a brief reference to the rocks will be sufficient.

On the whole the structure of the country as represented by the Triassic and newer strata is fairly simple, and the general easterly and north-easterly dips are subject to but little modification. A gentle anticline is indicated by the inliers of Cornbrash and Great Oolite between Bourn, Folkingham and Sleaford; and a more important flexure occurs between Alford and Claxby, where the Lower Cretaceous strata have been proved from well-borings to rise in

7696.

GEOLOGY OF LINCOLNSHIRE.

an anticline and to directly underlie the Drifts. To the east of Alford and Willoughby the Chalk is again present beneath the superficial deposits, and it extends below ground to the coast a little south of Skegness. In the Geological Survey Map a probable line of fault was originally marked between Claxby and Skegness. A fault, with a considerable downthrow to the north had been proved at Claxby, but its prolongation to the south-east in order to account for the Chalk below Skegness need not now be assumed in view of the anticlinal structure.*

Other faults have been met with here and there in various parts of the county, and these are indicated on the Geological Survey map. None appear to be of any great magnitude, but they may be of sufficient importance to influence local supplies of water.

It is probable that the whole of the Fenland south of Bardney and Wainfleet is directly underlain by the Oxford, Corallian and Kimeridge Clays. Beneath this group of clays, or the lower part of them, the Great Oolite series and the Lincolnshire Limestone have been proved in certain places, as at Woodhall Spa and further south. The Great Oolite series, judging from the record supplied by Mr. H. Preston of the well at Crowland, shows considerable modification, the Great Oolite Limestone being absent as limestone, though probably represented by clayey strata. The Lincolnshire Limestone also undergoes attenuation beneath the Fenland.

The principal water-bearing strata, if we exclude the superficial deposits, are the Triassic Sandstones, the Lincolnshire Limestone, the Great Oolite Limestone, the Spilsby Sandstone, and the Chalk.

Shallow wells in any of these formations may be liable to pollution, but in the deeper wells, the supply when obtained from beneath an impervious covering, has had to travel for some distance underground, and is usually of excellent quality. In some cases, however, the deeper wells and also the shallow wells, are impregnated with mineral matter to an extent that renders the water useless for drinking purposes. This more usually happens when the water is derived from strata at a considerable distance from their outcrop.

The following are the geological formations represented in Lincolnshire :---

CARBONIFEROUS Coal Measures (sandstones, shales, and seams of coal).

CARBONIFEROUS.

The oldest strata reached by boring in Lincolnshire are the Coal Measures which were proved at South Carr by Idlestop, about three miles south-west of Haxey, at a depth of 1728 ft. 3 in. and penetrated to a depth of 3185 ft. 2 in. from the surface—the thickness passed through being 1456 ft. 11 in. The beds comprised shales, fire-clay, sandstones, ironstone nodules, and seams of coal.

PERMIAN.

Strata representing the Magnesian Limestone series, with sandstones and marls, were proved at South Carr in the deep boring of which particulars are printed further on. (p. 108.)

Owing to the abundance of gypsum, the water obtained from the formation would be exceptionally hard. The beds were met with at a depth of 1183 ft. 6 in., and penetrated to a depth of 1728 ft. 3 in., when Coal Measures were reached; the thickness of the strata regarded as Permian was 547 ft. 9 in.

TRIASSIC.

Bunter.

Red sandstone with pebbles, and with occasional bands of marl, was proved above the Permian series in the deep boring at South 7696.

Carr, at depths of from 746 feet 2 inches to 1183 feet 6 inches; indicating a thickness of 437 feet 4 inches of strata referred to the Bunter.

Bunter Sandstone was also reached at Gainsborough. There the supply from one bore-hole has not been sufficient for the needs of the district, and a second boring has been made.

The exposed areas of the Bunter lie to the west of the county in an isolated tract between Thorne, Doncaster, and Bawtry, and southward over a broad belt through Sherwood Forest to Nottingham.* The general thickness of the Bunter is here about 450 feet.

Keuper Sandstone.

Red and grey sandstones (sometimes in part grouped as Waterstones) with occasional bands of shale or marl, were proved at South Carr between the depths of 137 feet 7 inches and 746 feet 2 inches; the thickness being estimated at 608 feet 7 inches. It should be mentioned that the Keuper and Bunter Sandstones are often so closely connected that it is especially difficult to fix definite limits to them from the evidence furnished by cores. In the neighbourhood of Southwell, however, the Keuper Sandstones are much interbanded with marl, which would interfere with the free circulation of water, and their thickness probably does not exceed 80 feet.

Keuper Marl.

This division, the oldest of the strata exposed at the surface in Lincolnshire, consists of red and variegated marls with occasional bands of sandstone and locally some anhydrite and much gypsum. A thickness of 725 feet of Keuper Marls has been proved at Gainsborough, and the full thickness may be about 800 feet.

Local supplies of water are sometimes to be met with in the bands of sandstone which occur in the lower part of the series. A belt of these sandstones outcrops at Tuxford, to the west of the Trent valley. In some cases, as mentioned by Mr. F. M. Burton, where hard sandy layers are intercalated with the marls, the water that enters into a well may pass quickly away, and the well prove useless.⁺

The elevation of the land is 50 feet at Crowle Hill, 125 feet at Gainsborough Hill and near Epworth. The soil on these red rocks is for the most part a clay-loam.

^{*} See Dr. H. F. Parsons, "The Trias of the southern part of the Vale of York," *Proc. Yorksh. Geol. and Polyt. Soc.*, ser. 2, vii., p. 154, 1880; and "The Alluvial Strata of the Lower Ouse Valley," *Ibid.*, ser. 2, vi., 215, 1877.

^{† &}quot;Victoria History" of Lincolnshire, Art. Geology.

TRIAS AND LIAS.

Rhaetic Beds.

These beds include the following sub-divisions :---

| White Lias | - | - | - | - | - | - | - | | 3 | feet. |
|---------------|----------|------|-----|--------|-----|------|---|-------|----|-------|
| Black Shales | - | - | - | - | - | - | - | about | 25 | ,, |
| Grey Marls (m | erging i | into | Red | Keuper | Mar | :ls) | ~ | 5 to | 15 | ,, |

They are not water-bearing, as the White Lias is too thin to hold any useful supply.

LIASSIC.

Lower Lias.

This division consists in the lower part of alternations of limestones and clays estimated to be about 170 feet thick in North Lincolnshire, and about 220 feet thick in the southern part of the county.

Bands of ferruginous limestone and iron-ore, known as the Frodingham Ironstone occur above, to the thickness of 20 or 30 feet in the north, and not more than 5 feet in the south. These are surmounted by a mass of blue clay and shale which increases in thickness from less than 90 feet in North Lincolnshire to 450 feet or more in the south.

Only the lower portion of the Lower Lias, where the limestones are well developed, is water-bearing, and to a limited extent. The alternations of clay and shale prevent any considerable storage or circulation of water, and as a rule supplies are only obtained in shallow wells.

The ground rises to 117 feet at Messingham and 218 feet at Burton-upon-Stather. The soil is for the most part a stiff clay and loam, but a reddish loamy soil marks the outcrop of the ironstones, and from these small springs are given out.

Thackson's well, south-west of Foston, is a perennial spring that issues from the Lower Lias near a line of fault. There is a "petrifying" spring near Whitton. Owing to the difficulty in getting a ready supply of water, there are comparatively few villages on the clay lands occupied by the upper part of the Lower Lias and the lower part of the Middle Lias, as in the Brant valley, and again in the vale north-west of Lincoln where, however, the Lower Lias is much covered with Boulder-clay.

Middle Lias.

This is a variable division, comprising in the lower part micaceous and ferruginous clays and sands from 40 to 80 feet thick. In the upper part there are beds of ferruginous sandstone and ironstone which, however, are not persistent: they are 30 feet thick near Grantham, and are absent from Welbourne northward to Navenby and Lincoln. In North Lincolnshire the lowest layer is a band of ironstone (Pecten bed) which is taken as a convenient division between Lower and Middle Lias; while the rock-bed is a ferruginous limestone or ironstone from 6 to 8 feet thick.

The ironstone-beds and ferruginous sandstones known generally as the Rock-bed or Marlstone are water-bearing. The water is often very good, but it may be chalybeate. Owing, however, to the impersistent nature of this sub-division it can never be depended upon as a source of supply at a distance from the outcrop.

Where the Marlstone is present it usually yields a brown ferruginous soil.

Upper Lias.

The Upper Lias consists almost wholly of dense blue clays and shales with occasional bands and nodules of limestone, and with a few bands of limestone at the base. Its thickness in North Lincolnshire is about 25 feet, near Lincoln 80 feet, and at Grantham 120 feet.

The basement-limestones may yield a small amount of water which is not separable from that of the Marlstone, in well-sinkings.

OOLITIC.

Lower Estuarine Series and Northampton Sand.

This variable group comprises the following divisions :---

feet.

| Lower Estuarine Series. | Bluish-grey, black, purple, and green clay and shales, white sand, and sand-rock, with lignite and ironstone nodules. | 10 | to | 15 |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------|----|----|----|
| Northampton Beds (or Dogger) | Tough ferruginous sandstones, sands, loam and ironstone | 5 | to | 20 |

These beds hold a moderate amount of water. That from the Lower Estuarine Series is usually impregnated with sulphuretted hydrogen, but the Northampton beds yield good water in many places, and numerous springs are thrown out along their junction with the Upper Lias clay.

The upper and weathered (peroxidized) portion of the Northampton ironstone beds, as remarked by Professor Judd, are open and easily traversed by water, whereas the unweathered layers (carbonate of iron) below are less pervious but yield water, often copious springs, in the joints. The soft weathered rocks in this and other formations are sometimes termed "Kale" by quarrymen and well-sinkers. Near Lincoln the ironstone-beds are directly overlain by the Lincolnshire Limestone.

* See Geology of Rutland, Geol. Survey, p. 116.

OOLITIC SERIES.

Lincolnshire Limestone.

This is the chief water-bearing formation in the county, and indeed its yield especially in the neighbourhood of Bourn is so copious that there we find some of the best artesian wells in England. The Lincolnshire Limestone has a broad outcrop which is but little concealed by Boulder-clay. It extends through the county from Winteringham by Lincoln to Stamford, a distance of more than thirty miles, with a width of two to three miles north of Lincoln, and four to six miles on the south. Its thickness varies from 60 to a little over 100 feet, and rarely to as much as 130 feet.

In North Lincolnshire the following divisions have been made :--

Hibaldstow (=Ponton) Beds Oolite - - - - 20 Kirton Beds Grey limestones and clays with oolitic limestone at base- - 45

Near Kirton-in-Lindsey there is about 15 feet of grey shaly clay between the Kirton and Hibaldstow beds; south of Grayingham and Waddingham, as remarked by Mr. Ussher, the Lincolnshire Limestone becomes more homogeneous. From the fact that in this northern region it is subdivided by clayey beds, it does not yield such noted supplies of water as have been encountered further south. The northern portion is separated at Lincoln by the River Witham from the broader superficial belt to the south. Even at Lincoln and near Nocton there are soft marly beds in the upper part of the division. Underground the formation has been proved to extend eastwards below the Fenland as far as Crowland.

As remarked by Mr. W. H. Penning and Mr. W. H. Dalton, a glance at the Geological Survey map shows a series of villages along the escarpment of the Limestone and a similar series on or near the less regular line bounding the upper limit of its outcrop, their situation having arisen from the all-important condition of water supply. Water was readily obtainable on either side of the tract of open porous limestone in which it is supported on the west by the impervious Lias clay, and on the east by the absence of means of escape, the rock being waterlogged up to or near to the lip of overlying clay in the Upper Estuarine Series, and overflowing in powerful springs.* One of these is at Great Spring Head, S.W. of Dunston. Again to the N.E. of Lincoln, at Welton there are strong springs, one being marked on the map as the "Old Man's Head Spring." These springs, as stated by Mr. De Rance, show marked fluctuations according to the rainfall, proving the rapid circulation of water through fissures in the Lincolnshire Limestone. Thus the

* Geology of the Country around Lincoln, Geol. Survey, 1888, p. 45; see also De Rance, Proc. Yorksh. Geol. and Polyt. Soc., xii., 29. amount of water, as gauged by Mr. Teague, has varied from 105,000 gallons to 2,800,000 gallons (after heavy rainfall).* (See Fig. 1.)

| |

A. Upper Lins. B. Lincolnshire Limestone. C. Upper Estuarine Series, etc.

D, D, D. Line of perennial saturation, with springs at the points of intersection with the surface.

Mr. J. Addy mentions that "One of the main branches or tributaries of the River Glen has cut its channel partially through the Estuarine Clays for some miles above Braceborough Spa. This channel may be said to be a groove cutting more and more deeply into the clays, as the river falls in its course, and thus continually approaching the limestone under it, which bears the subterranean waters, until a point is reached when the stratum of Estuarine Clays under the groove, owing to its thinness, or perhaps 'faulty' nature, can no longer form an impervious division, or resist the upward force of the imprisoned waters. This point occurs in the river about 2 miles, measured up its course, above Braceborough Spa, and from it to the latter place the river is studded with springs, throwing up water with such force as to show distinctly above the surface of the rapidly-flowing stream. These eruptions, appearing at first singly, and at wide distances apart, gradually reach a climax lower down at 'The Caudles,' and again at Braceborough Spa, at both which spots the beds of the river, and of streams and pools adjacent, seem to some extent riddled by the number of vents for these waters."

"Mention ought also to be made of the noted 'Well Head' at Bourne, as a display of this water in the form of natural springs, yielding, when gauged in 1874, at the rate of 4,600,000 gallons in twenty-four hours. At Horbling, too, there is a natural spring of some note."

Among other examples are the Norcliff Spring at Wilsford, near Sleaford; the Lady Well at Ancaster; the Holy Well at Fulbeck, between Grantham and Lincoln; the springs that issue at the head

^{*} Proc. Yorksh. Geol. and Polyt. Soc., vol. xii., p. 32.

[†] Proc. Inst. Civ. Eng., lxxiv., 1883, 143.

of the combe, one mile and a quarter N.E. of Lincoln; and a spring at Stoke Rochford, near Colsterworth, south of Grantham, which is said to yield about 4,000 gallons a minute.

A "Blow Well" (see p. 15) is said to occur south-west of Hibal1stow.

The escarpment rises from 72 feet at Winterton to 250 at Sawcliffe, 239 at Hibaldstow Cliff, 227 at Hemswell Cliff, and 213 feet at Lincoln. In the area south of Grantham the Lincolnshire Limestone is much covered by Boulder-clay.

The soil is a brashy one with reddish-brown clay, and for the most part dry.

Upper Estuarine Series.

This division consists of white sands, coloured clays often green, shales with lignite, shelly marls, and limestones, with ironstone nodules at the base. In thickness it is from 20 to 35 feet.

Limited supplies of water are locally held in the sands and limestone bands, but the water, like that of the Lower Estuarine series, is not usually palatable.

Great Oolite Limestone.

This comprises hard shelly and occasionally oolitic limestones, with shales and marls; together having a thickness of 12 to 25 feet. The beds yield moderate amounts of water suitable for local supplies.

The Great Oolite Limestone forms a gentle escarpment, rising at Normandy Cliff to 126 feet. The formation disappears to the north of Brigg, and it is not persistent beneath the Fenland, being doubtless to some extent replaced by clayey and sandy strata. (See records of borings at Crowland and Deeping St. Nicholas.)

Great Oolite Clay.

Like the Upper and Lower Estuarine series this division consists chiefly of coloured clays, dark grey, purple and greenish, with also beds largely made up of oysters, and occasional seams of lignite. Ironstone-nodules often occur at the base. In thickness it is from 5 to 35 feet. The strata are not water-bearing, as there appear to be few sandy intercalations.

Cornbrash.

At the surface this appears as a rubbly fossiliferous limestone, and like other limestone strata it occurs in more solid layers at a depth. It is from 3 to 15 feet thick and locally yields small supplies of water. It diminishes in thickness towards the north.

Oxford Clay and Kellaways Beds.

The Kellaways beds at the base of the Oxford Clay consist of an alternating series of buff sandstones, sands, loams and clays, with usually clay or shale from 7 to 18 feet thick at the base. The sandy beds may hold a useful amount of water, where they are prominently developed, as near Sudbrooke Holme; but as a rule the supply would be small, and it is seldom good in quality. The Oxford Clay consists of dense clays and shales with septaria, and varies in thickness from about 300 feet in North Lincolnshire to 400 feet and perhaps more in the southern part of the county. The Oxford Clay is impervious, and the soil is a heavy clay. The formation is, however, largely concealed by Boulder-clay and other Drift deposits.

Corallian.

This division, represented in Lincolnshire by black clays with much selenite, is about 15 feet thick, and is impervious. It is largely concealed by Boulder-clay.

Kimeridge Clay.

This formation comprises dark shaly clays and bituminous shales with septaria, and is about 320 feet thick. It is almost wholly impervious, but at the brick-kiln near South Willingham, according to Mr. A. Strahan, "Below the layer of septaria there occur bands of hard inflammable oil shale, locally known as "dice." The bands are 4 to 6 inches thick, and are separated by blue clay. . . About Willingham water is got in some of the shallow wells from the beds of dice. Some of the water is ferruginous and smells offensively."

The formation is extensively hidden by Boulder-clay and other Drift deposits. The soil is stiff clay.

LOWER CRETACEOUS.

Spilsby Sandstone.

This division consists of green, white and brown sands and sandstones, the latter sometimes pebbly and indurated into a very hard calcareous grit : phosphatic nodules occur at the base.

It varies in thickness from 6 feet near Claxby to 50 feet on the south, and 20 feet near Spilsby. The Spilsby sandstone is a good water-bearing stratum, and numerous villages are situated along its outcrop, for, as pointed out by Mr. Jukes-Browne, strong springs gush out at many points along the line of its junction with the Kimeridge Clay. These springs are occasionally ferruginous.

In the dales on the western side of the Steeping valley, there are two springs which have attained celebrity, the "Lady Well" at West Keal, and the "Holy Well" at Somersby. In the case of the Lady Well the gathering ground appears to be about 150 acres

^{*} Geology of the Country around Lincoln, Geol. Survey, p. 81.

LOWER CRETACEOUS.

in extent, while the thickness of the Spilsby Sandstone is not more than 35 feet, and it is noteworthy how small a collecting area will support a perennial spring.*

Tealby Series.

This series is divided into :--

Tealby Limestone { Upper Ironstone and clay Roath Ironstone Clayby and Hundleby Ironstone.

The united thickness is about 225 feet at Skegness and 100 feet near Spilsby, and it may be said to vary from 135 feet at the southern end of the Wolds to a foot or two at Elsham, owing to the uncomformable overlap of the higher Cretaceous beds. The thickness at Tealby is 65 feet, near Nettleton 45 feet, and at Audleby 10 feet.

The lowest beds, which comprise the Claxby and Hundleby ironstone, consist of ferruginous clay with grains of oolitic iron-ore, and this iron-ore sometimes occurs in mass about 9 feet thick and sometimes as occasional beds in yellow loam 6 to 14 feet in thickness.

The Tealby Clay consists of tough blue clays with selenite, oolitic iron-ore and small septarian nodules; it is 28 feet thick at Tealby, 40 feet at Claxby, 70 or 80 feet thick near Dalby, and 180 feet or more at Skegness.

The Tealby Limestone consists of hard limestones with shaly partings. It is about 14 feet thick at Claxby, but thins away northward. It appears to pass into the Roach, a soft yellow ferruginous marl with grains of oolitic iron-ore, or into a hard ironstone or ferruginous limestone, estimated at from 20 to 40 feet thick.

The Upper ironstone and clay comprise local beds of clay with grains of oolitic iron-ore, and are about 25 feet thick.

The Tealby beds do not appear to furnish any noteworthy amount of water.

Carstone.

This division consists of red sand, sandstone, and pebbly gravel, 10 to 14 feet thick near Claxby, but thickening south-eastward, being 20 feet near Thoresway, 25 feet at Tealby, and 40 feet further south.

The strata are water-bearing, and springs issue from the base. At Rothwell south-east of Caistor there are springs which issue from an inlying tract of the Carstone.

The Lower Cretaceous rocks rise to 124 feet at Spilsby, to 200 feet at Tealby, 232 feet at Donnington-on-Bain, and 300 feet at Nettleton Hill. They were originally grouped as Lower Greensand.

^{*} Geology of East Lineolnshire, Geol. Survey, p. 135.

UPPER CRETACEOUS.

Red Chalk.

This is a bed of nodular and earthy red chalk 4 to 12 feet thick, with often at the base layers of red, green, yellow or grey marl or clay which serve to arrest the downward percolation of the water from the Red and White Chalk, and to throw out springs. "Sometimes water oozes out along the line of junction for a distance of many yards, but more usually it issues in considerable quantity at a single spot which is always in a deep recess or at the head of a valley."*

Chalk.

The Chalk is sub-divided as follows+ :---

Upper Chalk with flints (thickness not ascertained). Middle Chalk with flints, 80 to 100 feet. Lower or Grey Chalk, 75 to 80 feet.

The Lower Chalk consists of harder and softer beds of grey and white and occasionally pink chalk, and grey shaly marl. It includes in the middle a nodular bed with green-coated nodules, equivalent to the Totternhoe stone. In north Lincolnshire the thickness is about 70 feet.

The Middle Chalk, as pointed out by Mr. C. Reid⁺, extends along the eastern margin of the Wolds as an ancient buried and degraded sea-cliff, against which the Glacial deposits abut. This tract is part of the old bay of Holderness; and on the south-side of the Humber the cliff extends through Thornton, Ulceby, Keelby, Laceby, Hawerby, and Ludborough. The lower portion of this Chalk is a hard greyish or yellowish chalk without flints, about 10 to 15 feet thick, the main mass, 70 or 80 feet thick, is a white compact chalk with layers and scattered nodules of grey flints. There is no distinct representative of the Melbourn Rock.

The Upper Chalk, the extent of which has but recently been recognised by Mr. William Hill, consists of firm and hard chalk with softer layers and occasional bands of grey marl. Nodules and large lenticular masses of grey flint occur, the latter being tabular and forming continuous floors over considerable spaces. They are liable, therefore, to interfere with the free circulation of water.

Mr. Jukes-Browne remarks that no exposure of the Upper Chalk is known to exist in that part of the Wolds south of Louth, but some portions may be present on the high ground between Driby

‡ Geology of Holderness, Geol. Survey, 1885, p. 1; see also Geology of parts of North Lincolnshire, etc., Geol. Survey, 1890, p. 113.

^{*} A. J. Jukes-Browne, Geology of East Lincolnshire, p. 136.

[†] For details see Jukes-Browne, Cretaceous Rocks of Britain, Geol. Survey, vol. ii., pp. 216, 478; vol. iii., p. 271.

and Rigsby. Upper Chalk occurs at North Elkington, Fotherby, North Ormsby, Wyham, Hawerby, Wold Newton, East and West Ravendale, Hatcliffe, Irby, Riby, and in the neighbourhood of Kirmington, Burnham, and Barrow-upon-Humber. It also extends eastward beneath the Glacial and Alluvial deposits of this northeastern part of the county.

Mr. Jukes-Browne points out that while in Lincolnshire the escarpment of the Chalk is a conspicuous feature, yet "the thickness of Chalk which crops out below its summit ridge is small (less than 100 feet), and the greater part of the frontal slope consists either of Lower Cretaceous beds or of Jurassic clays, according as the Chalk oversteps the one series on to the other." Thus the escarpment of the Chalk is only the upper part of the slope which forms the descent from the Wolds. Again, there is seldom any second slope or rise from the outcrop of the Lower Chalk to that of the higher beds of Chalk, "and as a rule the escarpment ridge is the dominant feature, forming a continuous watershed, and separating the valleys of the Wolds from those of the country to the westward."

"There are, however, two breaks in the continuity of the escarpment, one near the southern end, where the valley of the Calceby beck cuts completely through the Wolds, running from west to east; the other north of Donnington, where it is deeply indented by the head waters of streams which unite to form the river Bain. Beyond this point, and all through North Lincolnshire, there is a continuous escarpment ridge, except that at Melton Ross there is a well-marked depression or pass, which appears to be a truncated valley. Everywhere the frontal edge of the escarpment is a more or less sinuous line, with frequent combes and recesses, which have been eaten out by the action of rain and springs.* "

The following are some of the elevations attained by the Chalk Wolds :---

Saxby Wold, 329 feet Elsham Hill, 300 feet. Somerby Top, 300 feet. Audleby Top, 331 feet. Fonaby Top, 463 feet. Normanby-le-Wold, 548 feet. Bully Hill, near Tealby, 461 feet. Near Gayton-le-Wold, 453 feet. Goulceby Top, 455 feet. East of Cawkwell, 488 feet. Rosin Hill, West of Oxcombe, 427 feet. Tetford Hill, 468 feet.

Mr. Jukes-Browne has further pointed out that "On the Chalk Wolds no water is obtainable without sinking through the Chalk into the Carstone, and along the central part of the range or

^{*} Cretaceous Rocks of Britain, vol. iii., p. 413.

watershed the supply so obtained is often very small, and runs short in the summer time, although the springs at the outcrop con-This is the case along the high ground near tinue as usual. Ulceby and Driby High Barn west of Alford, where the Chalk is over 200 feet thick. The reason of this is probably that the water which falls on the Chalk, and reaches the base of that rock, makes its way quickly either to the west or east, so that in dry seasons little is left along the central line beneath the watershed. In the winter the supply is generally abundant, and where the Wolds are trenched by deep valleys, as near Burwell, Haugham and Maidenwell, intermittent springs and winter-bournes often make their appearance," as in the case of Skirbeck.

As remarked by Mr. Reid, the water supply on the eastern side of the Wolds is mainly obtained from three sources :--natural springs from the Chalk, "blow wells" on the low lands, and artesian borings which tap the Chalk underlying the Drift. Along the eastern slope of the Wolds many powerful springs rise, but several of them being intermittent are quite untrustworthy for water-supply.*

Fuller reference has been made to these waters by Mr. Jukes-Browne, who observes that strong springs break out along the line where the Boulder Clay is banked up against the cliff or steep slope "As the depth of Boulder-clay at a few hundred yards of Chalk. distance from the boundary line is from 60 to 90 feet, it is evident that this impervious mass obstructs the flow of the water which is percolating eastward through the Chalk, and forces much of it to the surface; the result is that a number of perennial springs, affording an excellent and abundant supply of water, break out at those points along the line where the level of the ground is lowest, and generally where one of the dry valleys that trench the Wolds opens on to the Boulder-clav plain. It may be useful to give a list of these here, commencing with the southernmost :--

- 1. At Welton, west of the Church.
- 2. At Claxby, about 200 yards west of Church.
- 3. At Well, one furlong N.E. of Church.
- 4. At Haugh, about six furlongs N.N.W. of Church.
- 5. At Belleau, between the Church and the Hall.
- 6. At Muckton, 200 yards N.E. of Church.
- At Cawthorpe, by roadside below the Church.
 At Louth, Aswell, and St. Helen's springs.
- 9. At North Ormsby, near the Church.

"Besides these strong springs are thrown out under similar circumstances at Tathwell, Maltby, Raithby, Withcall, Welton-on-Wold, and at the Silver Springs west of Louth, where the town waterworks are situated."+

^{*} Geology of Holderness, Geol. Surv., 1885, p. 126.

[†] Geology of East Lincolnshire, p. 136.

More than fifty years ago Mr. J. A. Clarke observed that "as the chalk dips under the clays and marshes great numbers of wells have been sunk down to it in order to obtain good water with little trouble, and the purest fresh water rises plentifully through the borings to the level of the surface." He added that in some localities there are natural outlets called "blow-wells," "which furnish an unceasing supply of water from the chalk beneath."*

These, as pointed out by Mr. Reid, " are springs which rise through Drift or Alluvium in the middle of the flat lands. They generally bubble up from the bottom of small pools of perfectly clear water, and are connected with some porous bed considerably beneath the surface. The name probably refers to the constant play of the white sand at the bottom of the pools; for bubbles of gas are only disengaged in a few of them, and not, as far as I have seen, in the larger ones."

Attention was called to the blow wells in 1816 by Edward Bogg, who stated that "their depths have never yet been ascertained, but we cannot entertain a doubt of their communicating with the chalk. These wells overflow with a greater flux at the time of high water, and particularly at spring tides."[†]

During the construction of the Albert Dock at Hull great trouble arose from "boils" or "spouts" at the base of the excavation, which, charged with yellow sand, burst into the works. The water was brackish, but it was regarded as due probably as much to land water as to any connection with the Humber.[‡]

The following particulars are given by Mr. Reid :---

"South of the Humber there is a Blow Well about a mile west of Barton, and another a mile east of the village, on the Warp. Perhaps the southern branch of Barrow Beck also rises in one, but there are also a number of artificial wells to supply the water-cress beds.

"Along the course of the Ulceby Beck there are several Blow Wells, which apparently rise out of the Inter-glacial Gravels, where they pass under the Boulder Clay. Two of these are on the Alluvium at Thornton Moor, and there is a group on the Alluvium south of Ulceby; these latter may rise either from the Gravels or directly out of the Chalk.

"Keelby Springs also rise near the point where the Boulder Clay overlaps the Gravels, and so does a Blow Well on the Alluvium north of Laceby. Along Laceby Beck there are several Blow Wells, all probably rising from this bed of Gravel, which must be close to the surface, though not always actually bare.

"Between Grimsby and Little Coates lie the group of Blow Wells which now supply Grimsby with water. They form several pools

+ Trans. Geol. Soc., vol. iii., p. 394.

^{*} Farming of Lincolnshire, Journ. R. Agric. Soc., xii. (1851), 273.

[‡] J. C. Hawkshaw, Proc. Inst. Civ. Eng., xli. (1875), 98.

of clear water, which yield a supply sufficient for the town, though a great deal runs to waste. These wells are more than three miles from the bare Chalk, but they occur at a point where the Interglacial Gravels again outcrop.

"The origin of the Blow Wells just described is not satisfactorily made out, for the bed of Gravel from which they appear to spring has a small outcrop, and is quite incapable of yielding so large a supply of water; there is also ne evidence of direct connection with the underlying Chalk. The most probable explanation is that the water is Chalk water, not obtained direct, but flowing for a mile or more through the Gravel, which abuts against the buried Chalk cliff below the line of saturation. The thinning-out and overlap of this Gravel as we go eastward will account for the same springs not being tapped in the numerous borings which pass through the Boulder Clay, and obtain their supply from the Chalk. Occasionally the springs are tapped. Mr. Cordeaux, on deepening the cellar of his house at Great Coates, broke into a bed of sand, which yielded so copious a supply of water that it needed the laying down of a special drain to carry it away.

"Close to Tetney there is a group of seven or eight Blow Wells on the Warp, the origin of which is much more difficult to understand. A farmer stated that he had lowered a heavy weight to a great depth in one of them, and found no bottom. There is also no trace of the Gravel in the immediate neighbourhood; and Mr. Jackling states that close to the Wells he bored 63 feet in clay before reaching the Chalk, and at Tetney village there was 81 feet of clay. From this it would appear that at Tetney Blow Wells the water must rise direct from the Chalk. How the water has penetrated the 63 feet of clay is not clear, but probably these Wells originated when the land was at a higher level, and instead of an Alluvial flat at this point there was a steep-sided valley cut 40 or 50 feet lower perhaps sufficiently low to tap the Chalk or an immediately overlying sand bed.

"Though the natural water supply of Holderness is, as a rule, not good, an artificial supply is so easily obtained, and the mode of obtaining it so well understood, that nearly every farm has a well down to the Chalk.

"These wells are usually bored through an average thickness of 70 or 80 feet of Drift or Warp, and water is generally found within 20 feet of the top of the Chalk. On the low grounds the water often overflows directly the Chalk is reached. The borings are made very cheaply, so much so that six or seven have been made merely to supply the watercress beds at Barrow.

"At Sunk Island (on the Yorkshire side of the Humber) the water from the Chalk is brackish. But this does not appear to be the case elsewhere on the borders of the Humber, for there are numerous wells of good water on the warp lands of Lincolnshire.

GLACIAL DRIFT.

"Wells on the Humber Warp near Great Coates are sometimes affected by the tide, but none of them appear to be brackish.

"Close to the pier at Cleethorpes there is a boring which supplies a drinking fountain. Formerly this yielded 200 gallons in five minutes, overflowing 2 feet above the surface; but the supply is now much less, the bore having apparently become clogged. Another boring at Cleethorpes, in the bed of the Humber, 400 yards below high-water mark, yielded 100 gallons per minute, forcing a jet 16 feet higher than the ground. There is another similar well on the warp near Humberstone."*

SUPERFICIAL OR DRIFT DEPOSITS.

PLEISTOCENE.

Glacial Sand and Gravel.

These deposits comprise fine and coarse gravel and sand, with flints, quartz, quartzite, and fragments of Jurassic rocks and fossils, also occasional boulders and layers of loam or clay. The thickness varies from a few feet to 30 feet and upwards. There are gravels and sands above as well as below the Boulder clay, and occasionally water is obtained from irregular seams of sand and gravel in the Boulder clay. In certain areas the Glacial sands have been winddrifted, as on Nettleton Common.

Springs that issue from the Glacial Drift are of variable quality, the waters being sometimes unpalatable, from the presence of salts of iron, etc., but good local supplies are often obtained from them and from wells.

Boulder Clay.

Much of the Boulder clay is a tough tenacious clay, brown, bluish-grey and purple, with numerous fragments of chalk, flints, and many stones and boulders, and sometimes with large transported masses of rock. On the Wolds the Boulder clay is for the most part very chalky, while on the eastern side of these hills it is a brown stony loam, sometimes termed the Hessle Beds.

The thickness reaches 30 feet, or more, as in some cases the Boulder clay occupies deeply eroded hollows. It extends over a good part of the vales of the Lias, Oxford and Kimeridge Clays, over the southern tracts of Lincolnshire Limestone, and along the eastern borders of the Chalk Wolds.

Valley Gravel.

These gravels do not differ materially in composition from the Glacial gravels, but are more generally stratified. Beds of loam are occasionally met with.

^{*} Geology of Holderness, pp. 128-130, 7696.

Mr. J. A. Clarke has remarked that, "From Tattershall, through Coningsby, Tumby, Mareham, Revesby, etc., the same sandy gravel forms the surface, except in those places where the clay is left bare. In these and neighbouring parishes there is everywhere plenty of water, which breaks out of the hills in springs, and these, if not cut off, find their way into the fens below."* Good local supplies have been obtained from wells, but these are liable to pollution, especially in towns and villages.

RECENT.

Blown Sand.

Much wind-drifted sand occurs inland as well as on the sea-coast, and sometimes attains a thickness of 50 feet. Inland it occurs along the foot of the great escarpments of the Chalk and Oolites, and sometimes it is banked up against the slopes.

Mr. Jukes-Browne observes that

"Along the landward edge of the sand hills which border the coast fresh water is often obtained in shallow wells. This is the case at Skegness, Sutton, Mablethorpe, and other places, and there can be no doubt that the supply is derived from the local rainfall stored up at the base of the sand hills, though the width of these is in many places less than 100 yards. The supply is generally sufficient for the cottages built near the sand hills and only fails in very dry seasons."[†]

Alluvium.

The Alluvium is composed of peat, clay, marl, and silt, the silt giving rise to a lighter soil of sandy loam or "warp," which holds a small amount of water. The strata are irregular and variable, and they attain a thickness in places of 50 feet or more.

The estuarine waters of the Humber are bordered by alluvial flats and salt marshes, drained by the Idle and Torne, and by numerous artificial channels, and formerly by the Don.[‡]

In the marshland of North Lincolnshire (Isle of Axholme Rural District) the alluvial strata, noted by Dr. H. F. Parsons, commonly comprise from above downwards :---

- 1. Warp, naturally or artificially deposited.
- 2. Peat.
- 3. Sand.
- 4. Laminated clay, often of considerable thickness.
- 5. Sand and gravel.

* Journ. Roy. Agric. Soc., xii., 276.

† Geology of East Lincolnshire, p. 137.

[‡] Dr. H. F. Parsons states that the old Don, though still spoken of locally as "the river Dun," is now silted up, and its course in most places is scarcely to be traced. It does not serve as a drain at all, but its site still forms the county boundary, and the villages are situated along it. See footnote, p. 4. Shallow wells have been constructed in these strata in many places, but owing to the defective drainage the water, especially that taken from above the laminated clay, is liable to pollution.

The amount of Alluvial lands in Lincolnshire has been estimated at upwards of 500,000 acres. Much of the land is but 9 or 10 feet above O.D., and rarely as much as 20 feet; and some of the levels vary from 4 to 16 feet below high-water mark of the German Ocean. The country is intersected by dykes.

The peaty areas have "a natural tendency to hold water and continue in a swampy state. The great district extending between Lincoln, Wainfleet, Deeping, and the Nene estuary, is of this conformation." There is peat also in the Trent and Ancholme valleys.

The rivers pour down, in wet seasons, the accumulated floods "upon the fens at their lowest points, when they at once lose their velocity and momentum." It has therefore been necessary to conduct them across the lowlands between high and strong embankments. "Nevertheless the fall thus secured is very trifling, only from three to four inches per mile." Barrier banks have been erected to fence out the tides, and means have been provided for drawing off the water. Thus the Ancholme has been straightened and turned into a canal called the New River.

The marsh grounds have been embanked, "and the issue of the land-waters regulated by sluice-doors in the banks, emitting the freshes when the tide sinks beneath the level of the inside water, and preventing the ingress of the sea when risen above a certain level."*

A soaking in of saline water has affected many wells and ponds in the marshlands. The depth of the ground-water or "Soak" varies, but at times it rises to the ground-level.

Great difficulty has always existed in the Fenland areas in obtaining a proper supply of drinking water. Rain-water cisterns have been constructed, but in most cases it appears desirable, as Dr. Parsons has pointed out, that the water be filtered before entering the underground cisterns.

Dr. R. Bruce Low, writing in 1893, says that the water of the Trent is used for drinking purposes by villagers in the Gainsborough and Glanford Brigg Rural Sanitary Districts; and yet "almost from its source the Trent becomes polluted with sewage."

The water is drawn at low water, just before the tide begins to flow again, as the water is brackish at high tide. At spring tides, owing to the "Eygre" or tidal wave, good water cannot be obtained, and a stock is laid in beforehand.

Dr. Low concludes that in the regions bordering the Trent "Water drawn from the canal or from the rivers would seem especially dangerous; not only by reason of the known pollutions which have

^{*} The quotations above are from a paper by Mr. J. A. Clarke, Journ. Roy. Agric. Soc., xii., 289.

access to them, but also because the sanitary authority can have no power to prevent the pollution of these waterways by strangers suffering from communicable disease." Until safer supplies have been procured, "the best security to be had is obtained by boiling all water used for drinking purposes."*

The superficial areas occupied by the various geological formations in Lincolnshire have been calculated by planimeter, from the one-inch Geological Survey maps by Mr. Henry Dewey.

| | · Pervious and partially pervious. | Mainly impervious. | Percentage. |
|------------------------------------------------------------------------|------------------------------------|----------------------|-------------------------------------------------------------------------------------|
| Alluvium and Gravels Boul ler Clay | 1241.65 | 526.31 111.79 | $ \begin{array}{r} 47.37 \\ 20.07 \\ 9.01 \\ 4.26 \end{array} $ |
| Lower Oolitic Cornbrash Great & Inferior Series Oolite Series | 296.01 | | 11.29 |
| Liassic | | 191.32 18.71 | 7·30 •70 |
| | 1773.91 | 848.13 1773.91 | |
| | Total area | 2622.04 | |

The results are as follows, the areas being given in square miles :-

From this statement it appears that the pervious and partially pervious formations occupy about $\frac{2}{3}$ of the superficial area, and the mainly impervious formations about $\frac{1}{3}$ of the area. The Alluvial areas have elsewhere (p. 19) been estimated to occupy about 800 square miles, so that the various Gravels and Sands would extend over about 400 square miles. It should be mentioned that the area of the county in 1891 was given as 1,693,547 acres, or a little over 2,646 square miles; and that the above estimates are based on that area, exclusive of the recent marine sand and shingle.

The area of registration for the county in 1901 is given at 1,659,930 acres, or a little over 2,593 square miles.

The following statistics with regard to the county (taken from the Agricultural Returns, Board of Agriculture, 1904) may be of interest:

| Year | Area in Cultivation. | Area under Corn Crops. | | Area under Fallow. | Area under Permanent Grass. | |
|--------------|----------------------------------|------------------------------|------------------------------|----------------------------|-----------------------------------|--|
| 1900 1904 | 1,518,195 1,520,392 acres. | 562,504 553,426 acres. | 249,247 241,356 acres. | 18,388 34,163 acres. | 499,203 504,783 acres. | |

* Report to Local Government Board, 1893.

THE RAINFALL OF LINCOLNSHIRE.

BY HUGH ROBERT MILL, D.Sc., LL.D.

Secretary Royal Meteorological Society, Director of the British Rainfall Organization.

The accompanying Map represents the distribution of rainfall over Lincolnshire as the average of thirty-five years' observations, the period running from 1868 to 1902. The data were collected for the most part by the late Mr. G. J. Symons, F.R.S., who founded the system of obtaining and publishing rainfall observations in the British Isles known as the British Rainfall Organization, and they were published annually in "British Rainfall."

The Great Central Railway has set an example which other railway companies might follow with advantage in maintaining observations of rainfall at most of the railway-stations, and it is mainly due to this fact that the rainfall of Lincolnshire can be treated in such detail. Private observers belonging to all classes in the community have also kept up observations, sometimes for long periods.

In Lincolnshire there are thus many long records of rainfall running through the whole period of thirty-five years, and these made it possible to calculate the relative wetness of each year compared with the average. Expressing the average at each station as 100 the relative wetness and dryness of any year can be readily recognised, no matter how different the mean rainfall at the various stations may be.

The stations for which ratios were calculated were grouped according to their geographical position as Northern, Southern, Eastern and Western. The mean ratio for each group is given in Table I., together with the average of the whole series. This average may be taken as an index to the fluctuations of rainfall for the county as a whole during the thirty-five years, 1868–1902. It is at once apparent that the first half of the period had a rainfall substantially above the average, while the second half had a rainfall on the whole below the average. The wettest year appears to have been 1880, with a rainfall 38 per cent. above the average, but in 1872 (the wettest year for the British Isles as a whole) the excess was 37 per cent.; and for 1882 it was 34 per cent.

The driest year, as in most parts of the country, was 1887, when the deficiency amounted to 35 per cent., while in 1874 and 1884 the deficiency was 27 per cent. The driest three consecutive years were 1887-89, which gave an average deficiency of 12 per cent.,

RAINFALL.

and the three years 1897-1899 were within one per cent. of being equally dry. This is an unusually small deficiency, as the deficiency for the three driest years usually amounts to 20 per cent.

In cases where the record extended over a period shorter than thirty-five years, the mean for the whole set of years available has been corrected by using the ratio-table so as to yield the computed mean value of the rainfall for thirty-five years. All the figures used in the construction of the Map have thus been reduced to a common period. There is reason to believe that the mean rainfall of any period of thirty-five years does not differ by more than about 2 per cent. from the mean of any other period of thirty-five years, and, therefore, for localities with a mean rainfall of about 26 inches, such a mean, if expressed only to the nearest half-inch, may be accepted as the true mean.

After being reduced to the same long period the rainfall values have been corrected for difference in the heights of the gauges above ground. This is particularly necessary in the case of Lincolnshire as almost all the gauges of the Great Central Railway are placed 3 feet 6 inches above the ground, while some old private gauges are as high as 6 or even 8 feet. The standard height for the receiving surface of a rain-gauge in the British Isles is 1 foot above the ground, and many experiments have proved that for every additional foot of height up to about 10 feet, there is a falling off of the catch of rain by about 1 per cent. The correction of 1 per cent. per foot above 1 foot has consequently been added, but no other correction has been applied to the figures.

There were altogether eighty-three stations in Lincolnshire, and on its borders, the records at which were sufficiently accurate and long-continued to justify their use in preparing the Map. From the data afforded by these stations, which were distributed over the county in a satisfactory way, lines were drawn including all places having a rainfall below 22.5 inches, and above 25.0 inches, 27.5 inches and 30 inches respectively. These lines as reproduced on a small scale map give as accurate a representation of the distribution of rainfall in the county as it is possible to obtain from existing records.

The following table shows the area occupied by each zone of $2\frac{1}{2}$ inches of rainfall, and the mean rainfall of the zone :---

| Zone. | | 7 | Square Miles. | Per cent. of total area. | Mean Rainfall of Zone. |
|------------------|---|---|---------------|--------------------------|---------------------------|
| Below 22.5 in. | - | - | 34 | 1.3 | 22.25 |
| 22.5 to 25.0 in. | - | - | 1409 | 53.6 | 24.00 |
| 25.0 ,, 27.5 ,, | - | - | 898 | 34.2 | 26.00 |
| 27.5 , 30.0 , | - | - | 236 | 9.0 | 28.50 |
| Above 30 in | - | - | 51 | 1.9 | 30.25 |
| Total | - | - | 2628 | 100.0 | |

RAINFALL.

From these values the mean rainfall for the whole county is found to be 25[‡] inches, and applying the mean ratios for various years from Table I. we get :---

| 1868-1902. | Mean average Rainfall for Lincolnshire | 25·25 in. |
|---------------------------|-----------------------------------------------------|-----------|
| 1880 and 1872. | Maximum average Rainfall for Lincolnshire - | 34.70 ,, |
| 1887. | Minimum average Rainfall for Lincolnshire - | 16.40 ,, |
| 1887-1889 and 1897-99. | Driest 3 years' average Rainfall for Lincolnshire - | 22.20 ,, |

Broadly speaking, the county falls into three divisions as regards rainfall: a dry strip running through the centre from south to north, a wetter belt to the west running from south to north along the Oolitic escarpment, and a still wetter area on the east occupying the whole of the Chalk Wolds.

The dry central belt may include a narrow strip of 22.5 inches, or scarcely more, running from near Woodhall Spa in a winding path to the southern boundary, but the observations available do not justify us in showing it farther south than the railway joining Sleaford and Boston. Although the rainfall of the central strip exceeds 25 inches in the north, it is only by half an inch or so, and right up to the Humber it remains somewhat lower than on the Lincoln Cliff to the west or on the Wolds to the east.

A break is shown in the belt exceeding 25 inches near Grantham, but the rainfall in the gap does not appear to be less than 24.5 inches. The hilly ground to the south, however is distinctly wetter than the long narrow ridge of the Lincoln Cliff, to the west of which the flat valley of the Trent is markedly drier. It is probable that the gap in which part of Lincoln stands has a rainfall appreciably lower than 25 inches, but this is the case on so small an area that it is impossible to indicate it on a map of the scale employed.

The wettest part of Lincolnshire is undoubtedly on the Wolds, where the area with a mean rainfall exceeding 27.5 inches, measures 28 miles from south to north, and 11 miles from west to east, and includes almost all the ground which exceeds 100 feet in elevation. Immediately to the west of Louth the rainfall slightly exceeds 30 inches, and this must be the case over an area measuring 11 miles by 5 at least. Possibly the area should be extended 4 miles or so to the north-east, but as no part of it appears to have a fall exceeding 31 inches, it seemed safer not to exaggerate its importance by drawing the line any farther than the available figures absolutely warranted. Probably no part of the Wolds more than 400 feet above sea-level has a rainfall appreciably less than 30 inches.

It must be remembered in studying the isohyetal lines of Lincolnshire that the whole range of rainfall between one place and another is extremely small, not more than 8 inches, and that consequently, it is rarely possible to draw the lines with any certainty that they might not be equally accurate a mile on one side or on the other of the position they occupy.

RAINFALL.

As the stations from which the map was compiled are sometimes so close together that it is necessary to take the mean of several in order to obtain the figure for the spot in question, and as a few short records were taken to fill wide gaps between long-established stations, it is unnecessary to print all the values which have been utilised. Table II., however, gives particulars of a selection of typical stations including the wettest and the driest.

The importance of the rainfall of Lincoln as a source of underground water is enhanced by the fact that the lower ground on which the rainfall is least, is usually covered with impermeable clays, while the higher land, on which the amount of rainfall increases in close sympathy with the altitude, contains outcrops of the eminently permeable Oolitic strata and Chalk.

It is well known that the absorption of rain by the rocks depends to a considerable extent, upon the season. In summer, when evaporation is at a maximum and plant-life is making its greatest demands on the rain as it falls, there is practically no absorption, hence it is important to ascertain the seasonal incidence of the rain.

Table III. gives the mean monthly rainfall for thirty-five years, or nearly so, at six typical stations representing all parts of the county. The figures are not corrected for the height of the rain-gauge above ground; but a supplementary table gives the monthly falls expressed as a percentage of the annual total, and these values may be taken as correct.

It is seen that in almost all stations the month of highest rainfall is October, the only exception being July in one instance; but the column of maximum monthly rainfall shows how frequently very heavy falls occurred in all the summer months as the result of thunderstorms. The lowest monthly rainfall occurred in March or April in all cases. The monthly values expressed as percentages of the annual fall, give the clearest view, and the average percentages in the last column may be taken as a very close approximation to the monthly incidence of rain over the county.

It will be noticed that the stations on the Wolds have the greatest percentage of winter rain, those in the Fen the greatest percentage of summer rain.

(See Map at end of vol.)

WELL SINKINGS AND BORINGS IN LINCOLNSHIRE.

- [The groupings of Strata have been added by Mr. A. J. JUKES-BROWNE, Mr. H. PRESTON, Mr. C. REID, Mr. A. STRAHAN, Mr. C. FOX-STRANGWAYS, Mr. W. A. E. USSHER, Mr. W. WHITAKER, OR Mr. H. B. WOODWARD.]
- NOTE.—The Maps referred to are (1) the old series Geological Survey Maps, (2) the new series one-inch Ordnance Survey Maps, and (3) the Ordnance Survey six-inch maps.

Aby.

(1 in. Map 84, N.S., 103; 6 in. Map 66 N.W.) Well at the blacksmith's house. Information obtained on the spot.

Dug through [Drift] clay into gravel - - - 26

Alford.

(1 in. Map 84, N.S., 104; 6 in. Map 66 S.E.)

1. Well at Mr. Soulby's brewery, yielding a good supply of water. Communicated by Messrs. Baker & Son.

| | | | | | | | | | | Ft. | in. |
|-----------|---------|---------|--------|--------|----|---|---|----|---|----------|----------|

Water occurred (1) in the Chalk, (2) in the gravel beneath, and (3) in the greenish silty clay. The bore was plugged with clay to the base of the mass of Chalk, and this yielded a satisfactory and sufficient, though not abundant, supply. The Chalk is a large boulder or transported mass.

Allington.

Appleby.

(1 in. Map 86, N.S., 80; 6 in. Map 11 S.W.)

The following borings, 1 to 4, were communicated by Mr. A. Atkinson; they were also furnished to Mr. Fox-Strangways by the Rev. J. E. Cross, with others, which are given farther on. Bore 3 is in the Oolitic area, south of

APPLEBY.

Appleby Station, and as its site, Spring Wood Lodge, is shown on the Ordnance Map (86), the positions of the other three borings are indicated with reference to it. The correlations are by Mr. Ussher; from the Northampton Beds (Dogger) downward they are tolerably certain.

5. Borings at Haverholme Plantation.

In Boring B, the beds under the Cornbrash are evidently given in so generalised a way that no correlation of Great Oolite Clays and Hibaldstow Beds could be attempted. The 60 feet of "Blue shale," in Bore A, appears to be Middle Lias, and the shale 15 feet 6 inches thick may be the sole representative of the Upper Lias.

Mr. Strangways furnishes the following notes :---

Nine sections (boreholes and shafts) nearly in a straight line between the Keeper's Lodge at Spring Wood and Appleby, were made by Mr. Winn to prove 7696.

35

ASGARBY-ASHBY.

the depth and nature of the Lias Ironstones. These sections, although tolerably clear for the divisions of the Lias, are not so for the Oolites above, probably from the fact of the very shaly character of much of the limestone which in these accounts seems to have been frequently entered under the name of " bind."

Asgarby (Sleaford).

(1 in. Map 70, N.S. 127; 6 in. Map 106 N.E.)

Boring on estate of the Marquis of Bristol, 1900.

Communicated in part by Messrs. Hamnett & Co.

Passed through 6 inches of sand at depth of 147 feet. Water "very salt" rose within 30 ft. of surface; a little more water met with at 201 ft. and again at 280 ft.

4. A boring at Aswarby made in 1886 by Mr. Jesse Clare was carried to a depth of 131 feet, into the Lincolnshire Limestone, and water rose above surface during part of year.

5. Mansion of Sir George Whichcote, Bart. 1904.

Communicated by Messrs. Barnes and Sharpe, Sleaford.

Water rose above surface 8 ft. but subsequently settled at ground level. Supply 6,000 gallons per hour of very good water.

BARROWBY.

No water being obtained a "water-finder" was brought, and he indicated a sot 20 yards away to the south where a supply would be found at a depth of 17 or 18 fest. A well was sunk 24 feet to the nodule-bed, and a 2-inch boring for a further depth of 26 feet (total 50 feet), all in blue clay. No water obtained.

2. Well at Barkstone Heath, in Farmyard.

(6in. Map 114 N.W.)

Made by Mr. Frank Hobson (well sinker).

Communicated by Mr. H. Preston.

Yield, 6 feet water in well. A good supply.

Barrowby.

(1 in. Map 70, N.S., 127; 6 in. Map 113 S.W.)

Dr. H. F. Parsons (in a report to Local Goverment Board, 1890) remarks that there appears to be no difficulty in finding a supply of water in any part of the village. The wells are of moderate depth, usually 30 feet or under, and water rises in them to from 3 to 15 feet from the surface. The strata pierced by the the wells, include (1) below the top soil, rubbly calcareous sandstone, locally called "skerry"; (2) clay or shale with one or two bands of ironstone; (3) grey rubbly rock, in which the largest and best supply of water is found.

1. Casthorpe Well.

Made by Mr. Frank Hobson (well sinker). 1892. Communicated by Mr. H. Preston, from measurements. Height above O.D. 352. Yield 1,000 gallons per twenty-four hours.

Water comes into the well on the north-west side at Bed A. This bed is the usual source of supply in Barrowby. The well was tested by Mr. Preston during August, 1901, as a probable source for village supply. The well had been standing unused for several years, and the water level was 18 feet from the surface. The daily yield decreased as the water was lowered, until after passing the water-bearing rock (Bed A.) not more than 1,000 gallons per diem could be obtained.

Total depth 326 feet 6 inches.

The entire series below the Drift belongs to the Kimeridge Clay. The Clays were nearly all dark coloured and highly fossiliferous. The fossils have been identified by Mr. E. T. Newton.

We have given all the material that was inflammable the name of Shale. (See Analyses p. 217.)

Our term "Inferior Shale" is when the material had as much bituminous matter as to burn with a flame, and "Shale" when it was more inflammable, and burned brightly and easily.

3. About 300 yards west of the church.

Communicated by Mr. James Freeborough, well-sinker.

Boston.

(1 in. Map 69, N.S. 128; 6 in. Map 109 S.W.)

The town was supplied in 1849 with water from a reservoir constructed by Thomas Hawksley to the south-west of Miningsby, about 120 feet above the level of Boston and twelve miles distant. "The reservoir, which covers an area of 34 acres, and contains when full about 75,500,000 gallons, was formed by damming back the water of a small brook. The gathering ground, which lies between the villages of Miningsby and Asgarby, covers an area of about three square miles, and consists mainly of agricultural land. The source of the brook by which the reservoir is fed is a spring near the village of Asgarby, which crops out at the junction of the green-sand (Spilsby Sandstone), and Kimmeridge clay. From this spring, however, there is not much flow except in the months of January and February. For the most part it is surface water alone that finds its way to the reservoir."* The reservoir and the greater part of the gathering ground are on Boulder-clay.

Thompson records that as early as 1568 attention was given to the subject of procuring water from a distance for the use of the inhabitants of Boston. In that year, according to the Corporation Records, "four aldermen and four common councillors were appointed to consider by what manner water might be brought from Kele Hill," while "The Mayor and William Derby were appointed at a subsequent meeting to travel with the Commissioners of Sewers, to see whether fresh water may be conveyed out of Hilldyke to the borough of Boston." Thompson adds that "There is not any later notice of either of these projects. How the town was supplied with water at this time is not known."

In 1705 reference is made to a cistern in the market-place "for the holding of fresh water for the furnishing of this borough."

"In 1747, Thomas Partridge was employed to bore for water in the marketplace. The attempt was relinquished after penetrating to the depth of 186 feet." (See p. 57.) "In 1783, and the two succeeding years, the Corporation spent £440 in another attempt to procure water for the town; the depth then reached was 478 feet, when, there being no prospect of success, the design was abandoned."[†]

* Dr. S. M. Gopeman, Report to Local Government Board, 1901; see also Pishey Thompson, The History and Antiquities of Boston, 1856, p. 102.

† The History and Antiquities of Boston, 1856, pp. 67, and 96-98.

Later and unsuccessful attempts to obtain water by boring were made in 1826-28. Particulars of some of these are herewith given.

1. Market Place, 1747 and 1783.

Communicated by James Limbird, Surveyor to the Corporation, *Phil. Trans.* lxxvii., 1787, p. 50.

Sunk and bored to depth of 186 feet from surface by Thomas Partridge, in 1747; and continued by George Naylor, well-borer, of Louth, 7 May to Nov. 1783. Well 6 ft. diam. at surface, 5 ft. at bottom, and 27 ft. deep.

Mari Saline water of small amount rose to within 255 feet of the surface, and was attributed to soakage from above. This was the opinion of John Farey as given in a letter to Sir Joseph Banks dated 1808.* Farey also remarks : "There is a material distinction to be observed with regard to the term gravel, which has hitherto been overlooked by most practical well-diggers and borers, for they call the rubble of any loose rock or small pieces of stony substance, which their augers or buckets bring up out of the earth, by the name of gravel The ragstone mentioned at 481 feet, and the gravel at 115 feet 2 inches of depths, were, as I conceive, only layers of the extraneous fossils or stony nodules called ludus helmontii, with which this clay abounds, and possibly these may, in this case, form such a continuous bed as to communicate with the sea, and produce salt-springs, because the layers of such nodules or clay balls, in the London clay strata, are known to produce small springs in several places in the wells of Middlesex and Surrey The chalk, small pebbles, and flints, if any such were really brought up from the depth of 1741 feet, could, as I conceive, have come there only by falling down the hole from the alluvial gravel first mentioned, after being detached by the friction and swagging of the rods, or by the nose of the auger in returning it into the hole; I see no evidence to contradict a supposition that many of these, denominated gravel and chalk, were in reality fragments and chippings of ludus helmontii [septaria], or of clunch. . . .

Farey gave good reasons for believing that the Bedford (Sleaford) Limestone [=Great Oolite] might be met with at a depth of 500 or 600 feet below Boston, and that at a lower level, the Barnack ragstone (of the Ancaster hills) [=Lincolnshire Limestone] "will doubtless furnish a powerful spring of water that under proper management in pipes, would rise, and supply every street and building in the town of Boston with water." He concluded that the strata passed through in the boring were :—

Ft.

Thompson quotes the following record of a boring stated (in the MS. Minutes of the Spalding Gentleman's Society), to have been made by Thomas Partridge in "1746," near the old leaden Corn Market Cross.[†]

The date of the above should no doubt be 1747 as given by James Limbird (*ante*, p. 57.)

2.—Market Place, 1826.

Trial borings made at expense of John Wilks, M.P. "His first operations were made very near the place where Naylor had unsuccessfully bored for water to the depth of 478 feet in 1785. After boring 560 feet, the attempt failed, through the breaking of part of the apparatus.

* Thompson's Hist. and Antiq., Boston, pp. 668-671.

† Op. cit., p. 666.

58

"The second trial was made near the churchyard, under the direction of Messrs. William Wedd Tuxford and Peter Tuxford, of Boston. This perforation was made to the depth of 565 feet; when, owing to some defect in the piping, which severed at the depth of 40 feet from the surface, a quantity of loose sand fell into the vacant space, choked up all below, and rendered further attempts, either to continue the project on that spot, or to recover the piping, entirely unavailing. Messrs. Tuxford commenced a third attempt within twenty-four hours of the failure of this second one. This was made on the western side of the Market Place but the great desideratum of a supply of water was not obtained."*

3. Western side of Market Place, 1828 (May 3rd to August 3rd). Bored by Messrs. W. W. and P. Tuxford. From Thompson's History of Boston, p. 673.

59

In the Memoir on the Geology of the Fenland (pp. 211, 279) Mr. Skertchly regarded the whole of the section of 572 feet to be in Fen Beds and Drift. The evidence was subsequently discussed by Mr. Jukes-Browne,* from whose remarks the following are quoted :—

"Depending on this record and mainly on the fact that between the depths of 523 and 530 feet 'clay shells and flints' are said to have occurred, Mr. Skertchly regards the section as giving evidence of the extension of the Glacial series to the enormous depth of nearly 600 feet below Boston.

"I cannot but think, however, that the evidence on which this supposition rests is too weak and uncertain to support so startling a conclusion.

"In Cambridgeshire, however, the term 'flint' is said to be sometimes applied to hard beds and concretions in the Jurassic clays.

"It is quite possible, not to say probable, that the greater part of this boring lies in the Kimeridge and Oxford clays. . . Beds of rock and sandstone are known to occur in and between these clays not far to the southward. . . .

"Now assuming that the lower part of the boring is in the Oolitic Series, it becomes important to determine, if possible, the base of the boulder clay; and in the first place it may be noted that the boring at Fossdyke (only 7 miles south of Boston) reached the bottom of this clay at a depth of 166½ feet, passing immediately into Kimeridge Clay with septarian bands which was bored to a further depth of $159\frac{1}{2}$ feet. If we examine the account of the Boston well we find that stones are repeatedly mentioned as occurring in the clay down to a depth of 190 feet, but that below this [level] there is no recorded occurrence of stones throughout a thickness of 294 feet. All this portion of the section is described as 'dark clay with shells,' except a band in the middle, 22 feet thick, of 'light slate-coloured clay with large shells.' Such a description applies far better to the Kimeridge or Oxford Clay than to Boulder Clay, for it would be surprising that no stones should have been met with in boring through a thickness of nearly 300 feet of Boulder Clay. Moreover, if we place the base of the Boulder Clay at 190 feet the section then agrees very fairly with the more recent and more accurately described boring at Fossdyke." [Fosdyke, see p. 97.]

"It was then pointed out that the real difficulty lay in the interpretation of the lower 88 feet of the boring, which is stated to have passed through a varied series of sands, clays, and rock-beds; and I suggested that these might be a local development of Corallian Beds between the Oxford and Kimeridge Clays. A reconsideration of the matter has, however, induced me to alter my opinion. The thickness of Oxford Clay which comes in beyond the western border of the Fenland in Sheet 70 [old series] is very small; its easterly dip is also so small as to be inappreciable in the brickyard exposures, and in all probability it becomes really nil under the central part of the Fenland. Now Boston is only about fifteen miles from the outcrop of the Kellaways Beds near Sleaford, and if we allowed a dip of half a degree throughout the whole distance (which is probably an excessive estimate) the thickness of beds brought in below Boston will be only 630 feet, which is only 58 feet more than the 572 feet proved. Moreover, the Kellaways Beds do consist of alternations of white sand, clay, and sandy rock, with fossils."

"Consequently I am now inclined to believe that this boring traversed the whole of the Oxford Clay and the Kellaways Beds, and may possibly

^{*} Quart. Journ. Geol. Soc., vol. xxxv., p. 418 (1879).

even have entered the Great Oolite Clay. The succession of formations pierced by this boring may therefore be summarised as follows":--

| | | Ft. |
|-------------------------------------|--------------------------------------|------------------|

(Boring in progress.)

Bourn.

(1 in. Map 64, 70, N.S. 143; 6 in. Map 140 N.E.)

1. Prior to the year 1856 Bourn was supplied with water partly from shallow wells, "but many of the houses were wholly dependent upon carts, which fetched water from a considerable distance. In that year a four-inch boring was made to a depth of 92 feet through alluvial soil, gravel and Oolitic strata, till it reached a stratum, 6 feet thick, of compact and hard rock, in passing through which, at 92 feet below the surface, the tool fell suddenly about 2 feet evidently into a chasm or hollow, striking upon the hard surface of the underlying rock. The water immediately rushed up with great force... The water rose at the Town Hall exactly 39 feet 9 inches above the ground." The yield was about 570,000 gallons a day.*

* J. Pilbrow, Proc. Inst. C.E., lxxv. (1884), 245. J. Addy, ibid., lxxiv. (1883), 160.

3. Top of West Street.

For the Waterworks, 1888. Made by Messrs. C. Isler & Co. Communicated by Messrs. Easton & Anderson.

Bored throughout, and tubed to the depth of $89\frac{1}{2}$ feet. Water flowed 4 feet above the surface. Yield at a depth of 99 feet about 300,000 gallons in twenty-four hours. Subsequently deepened to 120 feet, and gave 864,000 gallons a day.

3. Top of West Street-continuea.

Mr. F. S. Courtney (of Messrs. Easton and Anderson's) writes as follows: — "The water tapped in this district, at a depth of about 98 feet, is very plentiful and the standing level is in many cases as much as 20 feet above the surface. There are several borings in the neighbourhood, but I do not know of any of the former ones which were tight: in every boring I have examined, a large proportion of the supply finds its way up the outside of the bore-pipe, and, meeting with some of the more friable strata at a higher level escapes. In this boring a double lining has been provided (10 inches in diameter to a depth of $44\frac{1}{2}$ feet, the rest 5 inches in diameter and reaching nearly to the surface), a sound joint having been made between the two. The boring is, I believo, quite tight. Two borings, made in recent years, within a mile of this boring, for the Spalding Water Company, in which no special care was taken, are unsatisfactory."

According to *The Engineer*, vol. lxv., p, 181 (1888), "this town is the only one in the United Kingdom which gets its supply direct from the source without pumping," referring, of course, to well-supplies only.

4. Great Northern Railway Station.

Made and communicated by Messrs. C. Isler & Co. to Mr. Whitaker, 1895 Good supply of water, rising 19 feet above the surface.

6. Spalding Waterworks.*

Made and communicated by Messrs. C. Isler & Co., 1893-94.

? 78 feet above Ordnance Datum.

Shaft 6 feet, the rest a boring of 13 inches diameter.

Water rises 34 feet above the ground.

Chalybeate water was found at a depth of $65\frac{1}{2}$ feet and was shut out. The main springs were tapped at $78\frac{1}{2}$ feet, the water then rising very slowly and taking twenty-four hours to overflow. Deeper, the volume increased rapidly and the overflow was 1,872,000 gallons a day at the depth of 100 feet, 2,592,000 at 120, and over 5,000,000 at 134.

Brumby, Crosby, Frodingham and Scunthorpe.

Dr. D. A. Gresswell in 1885 (Report to Local Government Board) remarked that the wells "vary in depth from 7 to 18 feet. The soil at Frodingham and Scunthorpe for a depth of 2 or 3 feet is sandy, and contains 80 per cent. of silica and 20 per cent. of lime, organic matter, and iron; a thin layer rich in peroxide of iron follows, and then a hard stratified rock of some depth, and consisting of ferruginous limestone, beneath which there lies a blue shale. The wells are sunk into the stratified limestone. . . . A very large number of them ran dry last summer, and the greatest difficulty was experienced in obtaining water." Iron is generally present in the water.

(In this Report Brumby is spelt Bromby.)

Caistor.

(1 in. Map 86, N.S., 89; 6 in. Map 28 S.E.) Well and boring near the Old Mill, 1903. Communicated by Mr. Henry Preston.

"At a depth of 40 feet a bed of Chalk was encountered, the previous bore having been through sandy soil. On Tuesday, September 8th, water was struck, the well being then 90 feet deep, but as the flow of water was deemed insufficient boring was continued, and on Saturday morning, at a depth of 100 feet, a spring was reached which yielded 7,800 gallons per hour. The water appears to be of excellent quality.

145

CROWLE-DALBY.

At 145 feet water rose to within 5 feet of the surface.

Messrs. Strangways and Cameron consider that the uniformity of thickness assigned to the rock and clay beds in this section precludes reliance on the details, though the section is of importance as proving the presence of Keuper Marls so far west. The rock-beds appear to be shaly sandstones.

Cumberworth.

Deeping St. Nicholas.

(1 in. Map 64, N.S., 144; 6 in. Map, 147, N.E.).

Boring at Littleworth, about 1 mile south-west of church. 1894. Height above O.D. about 10 feet. Sunk 5 feet 6 inches, the rest bored. Completed November 26th, 1894.

Communicated by Mr. Henry Sykes, 66, Bankside, London. Water rose 2 feet above ground ; yield, 20 gallons per minute.

Saline water was noted at 264 feet.

ELKINGTON-FOLKINGHAM.

Elkington, North.

(1 in. Map 84, N.S., 103; 6 in. Map 47 N.E.)

At the farm formerly held by Mr. Kemp, near Boswell.

Communicated by Mr. Charles Wilkinson, of Louth (well-sinker).

Bored through white chalk and "greystone" into red chalk - 297

Epworth.

(1 in. Map, N.S., 88; 6 in. Map, 25 N.E.)

"There are many wells in Epworth; those in the lower part of the town, to the west especially, are seldom used for drinking purposes, the water being very hard and sometimes discoloured. Very generally rain water is used instead. . . . There are two public wells in Epworth sunk in the rock towards the higher part of the town, their depth being about 30 feet." *

Firsby.

(1 in. Map 84, N.S., 116; 6 in. Map 83 S.E.)

Gainsborough.

(1 in. Map 83, N.S., 101; 6 in. Map 42 S.E.)

1. Made by Messrs. E. Timmins & Sons, at southern end of town, near the river Trent. Date 1885-1887. Communicated in part by Mr. A. Timmins; see also C. E. De Rance, *Proc. Yorksh. Geol. Soc.*, xii. 25; and F. M. Burton, in "Victoria History" of Lincolnshire, article "Geology." Sunk 58 feet, the rest bored. Water level about 6 feet from surface when bore was first made. Yield up to 25,000 gallons per hour. Contains 32.20 grains of mineral matter per gallon.

| | Thicknes | s. Depth. |
|-----------------------------------------------------------------------------------------------------------------------|--------------------|-----------|
| (Soil (not noted.) | Ft. in | Ft. in. |
| [Keuper Marl] Red marls with much gypsum t 350 feet, and very little below Fine sandstones (partly micaceous | - 720 0 | 720 0 |
| [Keuper and Bunter Sandstones] with bands of red marl and a few small pebbles | - 320 0 s 300 0 | 1,515 1 |

174

The water, as stated by Mr. De Rance, is mixed in the well with some upper waters, to which its hardness is due. Its hardness on Clarke's scale is 25.76, of which 16.31 is permanent, and 9.45 temporary. There is every reason to believe that, if the whole of the water were derived from the Red Sandstone it would be found much softer.

The supply, as noted by Dr. L. W. D. Mair (Report to Local Government Board, No. 139, 1899), has been regularly supplied to the town since 1889, but "has at no time been sufficient to meet all requirements," and "it has been necessary almost always to supplement the supply daily by water derived from the river."

When pumping from a depth of 200 feet the water falls to 100 feet from surface.—Rest-level in bore hole 15.29 feet above O.D.

2. A second boring adjacent to the first, made (1894-1900) under direction of Mr. P. Griffith, by Messrs. E. Timmins & Sons, has been carried to the base of the [New Red] Sandstone beds, which were met with at a depth of nearly 1,500 feet from the surface. An abundant and excellent supply of water has been obtained. (*Water*, ii. (1900) 282.)

The following particulars were supplied by Mr. Perey Griffith to Mr. H. Preston:-

| | | | | | | | | | Ft. |
|---------------------|--------|------|-----|-------|---|---|---|---|------------|
| Surface deposits | | | - | - | - | - | - | - | 8 |
| Marl with gypsum | - | - | - | - | - | - | - | - | 718 |
| Sandstone (with mar | l band | s to | 987 | feet) | - | - | - | - | 789 |
| • | | | | | | | | - | |
| | | | | | | | | | 1,515 |

The rest-level in this Borehole, No. 2, when the pumping of about 22,000 gallons per hour takes place from Borehole No. 1 (96 feet distant), is 88 feet below the surface. The maximum yield from No. 2 Borehole (pump at 300 feet from surface) is about 30,000 gallons per hour.

3. Two boreholes made in 1881, on the east side of the Trent, 20 chains south of Gainsborough Bridge, in Ashcroft Field, near the Great Northern Railway Company's siding, were noted by Mr. W. A. E. Ussher :---

| Chalk, very hard | | - | - | - | - | - | - | - | 15 |
| | | | | | | | | | |
| | | | | | | | | | 75 |

Water rose from the Chalk 4 feet above ground in great quantity. At 24 feet from the surface there is only a yield of from 7,500 to 8,000 gallons per hour.

Second bore-hole east of Grimsby (Cleethorpes). See also p. 82. (1 in. Map 85).

| Stiff bluish-brown elay with Sand and gravel Chalk with flints, in beds | - | - | - | - | - | - | Ft. 84 15 125 |
|-------------------------------------------------------------------------------|---|---|---|---|---|---|------------------------|
| | | | | | | | 224 |

The top of the Chalk is very rotten and seems to be all broken up; it had to be tubed to 120 feet from the surface. Mr. De Rance states that "The yield from this boring is only about 180,000 to 192,000 gallons per day," and when this quantity is pumped, the neighbouring wells lose their supply of water .- Rep. Brit. Assoc. for 1895,

A boring was put down to a further depth of sixty feet, passing through soft blue clay and reaching soft sand, presumably the top of the Spilsby Sandstone.

Hale, Great.

(1 in. Map 70, N.S., 128; 6 in. Map 107 S.W.).

1. Town Well.

Communicated by Mr. J. Cocks. Bored 210 feet. All clay and dice [Boulder Clay and Sunk 21 feet. Oxford Clay.]

2. Boring made in 1898.

Communicated by Mr. Jesse Clare.

Height, 27 feet above O.D.

Water came up at 310 feet 3 inches at rate of 5,500 gallons in twenty-four hours, and on completion at rate of 37,000 gallons in twenty-four hours, with 11 lbs. of pressure 2 feet above surface.

On analysis the water was said to be excellent for a village-supply.

HARLAXTON-HAXEY.

Harlaxton.

(1 in. Map 70, N.S., 143; 6 in. Map 122 N.E.) Made by Mr. H. Hobson, (well-sinker), for the Warren Farm.

Communicated by Mr. H. Preston.

1. Well sunk 30 feet deep through Upper Lias clay. At the bottom of well the clay was shaly with bands of fine sand between the shaly layers. Water came in here, but was found to be polluted by the stables.

2. The well which now supplies the farm is about a quarter of a mile east of the premises, 33 feet deep through Upper Lias. Water stands 10 feet in the well, but the supply is very small.

Haxey.

(1 in. Map 86, N.S. 88; 6 in. Map 25 S.W.)

Boring at South Carr, three miles S.W. of Haxey, near Idlestop.

Communicated by Mr. Lionel B. Wells, M.Inst.C.E.

Completed July, 1893. by Messrs. Vivian. (Trans. Manchester, Geol. Soc., xxvii. 58, 1901.)

Hough-on-the-Hill.

(1 in. Map, 70, N.S., 127; 6 in. Map 104 N.E.)

Well at Brandon.

Communicated by Dr. Eaton to Mr. H. Preston.

Well sunk 40 feet, bored 40 feet: total 80 feet.

All in blue clay (Lower Lias). Touched rock at bottom, probably ironstone of zone of *Ammonites semicostatus*, and found some water, but it was heavily charged with salt.

Hougham, Long Bennington and Marston.

(1 in. Map 70, N.S., 127; 6 in. Maps 104, S.W. & S.E.)

"The wells are from 15 to 30 feet in depth, are drysteined with stone or brick, and are not protected by any impervious material, such as clay, placed externally. The water from these wells is partly derived from that percolating between the layers of limestone, which occur in the Lias clay in which the wells are sunk, but it is probable that the greater part of it is derived from the water of the overlying subsoil. This Lias clay contains a large amount of gypsum, consequently the water from many of the wells is very hard and has a nauseous taste. In *Long Bennington*, owing to the small number of the wells, and the hardness of the water from the river Witham for drinking and cooking purposes. This river, before it reaches Long Bennington, receives the effluent water from the Grantham sewage farm and liquid refuse from the villages of Marston and Hougham."—(Report by Dr. S. W. Wheaton to the Local Government Board, 1898.)

Howell.

(1 in. Map 70, N.S. 128; 6 in. Map, 107 N.W.).

Communicated by Messrs. Barnes and Sharpe, Sleaford.

Water rose 20 ft. above surface. Quality good, but with a slight percentage of "salt."

Lincoln.

(1 in. Map 83, N.S., 114; 6 in. Map 70 N.E.).

Supplied from impounding reservoirs, water "derived partly from springs and partly from a gathering ground of 2,000 acres, which is one-third of it cultivated and the remainder woodland." The Corporation have also power to take water from the Witham. (Sixth Rep. Rivers Pollution Comm. 1874, p. 367.)

It has been decided to bore at Boultham to obtain if possible a supply of water for Lincoln from the New Red Sandstone. See p. 63.

LINCOLN.

2 1 1

Ft.

"There are no springs in the lower part of Lincoln; the water obtained there by the sinking of wells is the river water, which is filtered through the sand bed." (William Bedford, *Mag. Nat. Hist.* N.S., iii. 1839, 555.) Dr. Thresh (*Water and Water Supplies*, Ed. 3, 1901, p. 372) mentions an Abyssinian tube-well, sunk at Lincoln by Messrs. Le Grand and Suteliff in 1894 to depth of 31 feet in sand: it yielded 200 gallons per hour, the water standing at 4ft. 6in. from bottom.

| | | | | | | 180 |

The well was sunk to the base of the sand and gravel, and the Lias was bored to the further depth of 140 feet. No water having been obtained from the Lias, the boring was abandoned. The present supply, which is plentiful, is derived from the sand and gravel, the well being supplemented by connected tube-wells.

4. The following series of borings along the Witham valley was made in 1879-80 for the Great Northern and Great Eastern Railways. They were communicated to Mr. Cameron by Mr. Samuel Abbott, C.E., of Lincoln.

The position of each boring is shown on the map Fig. 2.

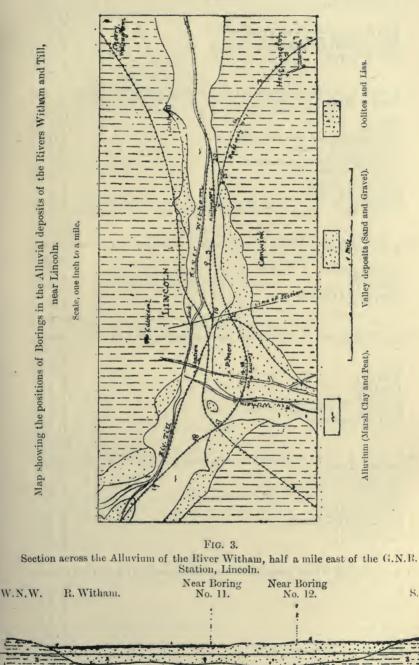

Details are not given of Borings Nos. 1 to 4, as they were made through ground that was subsequently removed in the railway-cuttings.

See Geology of the Country around Lincoln, Mem. Geol. Survey (1888), pp. 39, 50, 63, 66, 165, 197.

LINCOLN-LOUTH.

6. Cricket-field, Wragby Road.

Oolitic limestone (a few feet). Ironstone

Louth.

(1 in. Map, 84 N.S., 103; 6 in. Map, 48 S.W.).

1. Boring at the Waterworks, opposite Thorpe Hall, W.S.W., of Louth Church.

Communicated by Prof. H. Robinson, from a drawing made in December 1871, by Mr. T. W. Wallis, of Louth.

| | | | | | | Ft. | in. | |
|---------------|----------------------------|---|---|---|---|-----|-----|--|

| | Yellow sand | - | - | - | - | 8 | 0 | |
| | | | | | | | - | |
| | | | | | | 58 | 0 | |

Water was found in the Red Chalk from a depth of 17 to 25 feet, but very little came in from the sands below.

2. At the Windmill, half-a-mile N.E. of Church.

Well between 65 and 70 feet deep, entirely through clay into sand, with good water; Chalk not touched.

3. In Little Lane, Mount Pleasant.

Communicated by Mr. J. Bingley, of Aby (well-sinker). Dug 39 feet, bored 21 feet.

10. At Mr. Dickie's brickyard, three-quarters of a mile S.S.E. of Louth Church, in the valley.

(1 in. Map, N.S., 103; 6 in. Map, 56 N.W.)

Communicated by Mr. Dickie.

"The well was dug 18 feet, bored 32 feet, in all about 50 feet from the surface to the Chalk rock; through solid marl with small patches of sand here and there, but no regular beds. Water in abundance as soon as the Chalk was tapped."

A well at the brickyard east of the railway-station is said to have been dug 27 feet and bored 30 feet through clay to Chalk.

fe

Luddington.

(1 in Map., 86 N.S. 80; 6 in Map, 10 N.W.) Sunk in 1875, by Goole Rural Sanitary Authority. Site close to bed of Old Don River.

Communicated by Mr. E. C. B. Tudor, Surveyor, Goole, to Dr. H. F. Parsons, Proc. Yorks. Geol. and Polyt. Soc., vol. vi. 1877, p. 230).

Owston

(1 in. Map, 86 N.S., 88; 6 in. Map, 25 S.E.). Communicated by Mr. A. C. G. Cameron.

The relation of the surface deposits at Gunthorpe, as seen in drains appears to be :—

| Warp | - | - | - | - | - | - | - | - | - | 1 ft. to 15 ft. |
|------|---|---|---|---|---|---|---|---|---|-----------------|
| Peat | - | - | - | - | - | - | - | - | | 6 in. to 5 ft. |

Clay or Warp below again sometimes, but more often sand.

Wells yield hard water, furring kettles, so that Trent water is preferred and greatly used.

PILHAM-POINTON.

Pilham.

(1 in. Map, 83 N.S., 89; 6 in. Map, 35 S.W.).

Well at Farm house, about 300 yards from Blyton Station.

Communicated by Mr. Cressey, well-sinker, Scunthorpe, to Mr. Ussher.

| | | | | | | | | | 213 | 1 |

Communicated by Mr. Charles Hett, of Brigg.

The want of detail in this boring forbids the correlation of the beds with any degree of certainty. It is probable that limestones occur in the 18 feet 8 inches of clay, as such a development in the Kirton Beds is abnormal.

W. A. E. U.

SCUNTHORPE.

Scunthorpe.

(1 in. Map 86, N.S., 89; 6 in. Map, 18 N.E.).

Boring 1¹/₂ miles west of village. Made by Messrs. Vivian and Company. 1898-1901.

Communicated by Mr. W. Gibson from information afforded by Mr. A. McDonald Cobban, resident engineer.

Note by Mr. Preston, from information given by Mr. A. McD. Cobban:---Lining tubes were put in to a depth of 1,567 feet, all water above this point being excluded. Pumping tests were made and continued for fourteen days and nights, with the result that 300,000 gallons per twenty-four hours were obtained. This pumping reduced the flow from a slight Artesian head to a level of 160 feet down. Upon analysis the water was shown to be organically pure, but so excessively loaded with saline constituents as to render it unfit for a town supply (see Analysis, p. 211).

1. Waterworks-continued.

A fresh boring was made in 1903, and the notes in square brackets have been added from specimens sent by Mr. Jones and examined by Mr. H. B. Woodward and Mr. A. Strahan.

The yield at 321 feet was in September, 1903 at the rate of 2,300 gallons per hour; but in November, 1903, the average yield proved to be no more than 1800 gallons per hour,

2. Waterworks. Date 1886.

Communicated by Mr. Crawford (foreman in charge) to Mr. Whitaker. See Jukes-Browne, *Quart. Journ. Geol. Soc.*, vol. xlix., p. 472.

The "red marl" $(71\frac{1}{2} \text{ to } 91\frac{1}{2} \text{ ft.})$ probably includes pink as well as true Red Chalk, and possibly some Carstone mixed with red marl carried down by the boring tools. A sample from 297 feet was a hard oolitic marlstone with grains of iron-peroxide.

3. Boring at Seathorne (Nottingham and Notts.) Convalescent Home. By sea, 2,550 yards north-east of Skegness Waterworks. 1902.

Communicated by Mr. S. Coetmore Jones.

Height above O.D. 16 feet.

3. Boring at Seathorne-continued.

When the boring was 270 feet deep the water stood at 26 feet from the surface, when it was 321 feet deep the water level was 18 feet from the surface, and there seems to have been a very considerable increase of water at about 400 feet.

Skendleby.

1. Skendleby Salter.

(1 in. Map 84, N.S. 116; 6 in. Map, 75 S.W.)

Information from Mr. Belton (tenant).

No spring was reached here, but water trickles in from the side some way down. The lower part is probably in hard clay, as in well No. 2.

2. At cottage on Mr. Higgin's farm, Skendleby Salter, half a mile east of last.

Communicated by Mr. Ch. Wilkinson, of Louth (well-sinker). Dug 22 yards, bored 30 yards.

| | Chalk rubble | Ft. |
|-------------------------|-----------------------------------------------------------------|---------------|
| Carstone Tealby Beds | Brown soft sandstone [? and ironstone] - Black clay, dug for | - 24 - 126 |
| Teanby Deus | Diack clay, dug for | |
| | | 156 |

Two large oyster-shells were found at the bottom of the dug well; no spring reached in the boring. Mr. Tyson, of Willoughby, describes a bed of hard bluish rock, drying grey and flaky, "with silvery chips in it," as occurring in this well, probably at the base of the sandstone.

Sleaford.

(1 in. Map 70, N.S. 127; 6 in. Map, 106 N.E.).

1. Farey mentioned in 1808 that a boring was made "in search of coals some time ago, about $1\frac{1}{2}$ miles from Sleaford, by the side of the road towards London, which at a great depth tapped so powerful a spring, that the same has ever since boiled up a considerable height above the ground and given rise to a small brook."*

* Extract from letter to Sir Joseph Banks, printed in Thompson's History and Antiquities of Boston, 1856, p. 671.

Ft.

SLEAFORD.

Four-inch boring to depth of 120 feet. Water rose above surface.
 J. Addy, Proc. Inst. C.E., lxxiv. (1883), 161.

3. Mr. Chamberlain's, West Street.

Information from Mr. J. Cocks (well-sinker).

6. Boring at Messrs. Bass & Co.'s Maltings.

Communicated by Messrs. Le Grand and Sutcliff, who deepened the boring from 113 feet.

Good spring at 156 feet which rose $13\frac{1}{2}$ feet above the surface, with a flow of over 12,000 gallons an hour. On being deepened to 177 feet the bore yielded 30,000 gallons per hour. 1892.

| | | | | | 0 |

On February 9th, 1903, I visited this boring, and found that the water from the upper rock-bed (Cornbrash) had been tubed out and was running a constant stream into the drain. When the valve from the main supply was opened a supply of not less than 10,000 gallons per hour was running from the Lincolnshire Oolite.

Samples from this boring gave :

From Cornbrash-1.365 grains of chlorine per gallon.

From Lincolnshire Oolite-1.26 grains of chlorine per gallon.

H. P.

6. 2 in. Boring 1 mile cast of Railway Station.

Made by Mr. J. E. Noble, 1897.

Communicated by Mr. Preston.

Height above O.D., 29. Water level, 12 ft. below ground.

2. For Peterborough Waterworks, 1888-continued.

The supply previously available was pumped from a well 5 feet 6 inches in diameter, and the object of the present work was to augment the quantity by constructing artesian tube-wells and discharging into that well. (See under Braceborough).

Yield above noted was maintained to 1890 (date of Mr. Gill's paper.) During 1889, the volume of water pumped from the well [at Braceborough] into which the borings discharge, was 523,316,410 gallons. At commencement of year, the height of water in well was 51 feet 6 inches above O.D., and at end of year 52 feet $3\frac{1}{2}$ inches; the rainfall at pumping station in 1889 was 22.61 inches. The wettest month was May, when 5.01 inches of rain fell; and the maximum height of water in well (54 feet $10\frac{1}{2}$ inches) was reached on June 8. The minimum height (51 feet 5 inches) was reached on October 26. J. C. GILL.

|-------------------------------------------------------------------|--|--|---|--|--|
|-------------------------------------------------------------------|--|--|---|--|--|

At a depth of 33 feet a spring of salt water was tapped, resembling that of Woodhall Spa, but it gradually became less salt, and was finally replaced by a supply of fresh water.

2. Shaft and Bore-hole at Woodhall Spa. (6 in. Map 80, S.E.)

The following account of the Woodhall Spa was furnished to Dr. Granville by a physician resident at Horncastle :— "In the year 1819, some speculators, under the idea of finding coal at

"In the year 1819, some speculators, under the idea of finding coal at Kirkstead, near Horncastle, caused a shaft to be sunk at that place, 100 yards deep; they then bored 100 yards deeper, when the works were discontinued, as it was stated, for want of money. Immediately on the discontinuance of this attempt, a gentleman, owning an estate in the parish of Woodhall, about a mile distant from Kirkstead, was induced, without previously boring, to sink a shaft, thereon of 280 yards in depth.

"Boring was then had recourse to, which was carried 120 yards deeper. when this scheme, like all the preceding ones, was abandoned as hopeless, In this trial no regular account was kept of the strata passed through, but from the information and specimens received, it appears that the sinking was commenced in the clunch clay, which was found to be 120 yards in thickness; they then passed in succession through forest marble, combrash, oolite, Bath freestone, lias, clunch clay again ; then a rock, composed of carbonate of lime, siliceous sand, alumine, a greenish substance resembling chlorite, and a portion of mica, in which many terebratulæ were embedded [Marlstone]. In this rock, the sinking was discontinued. Of the boring no other account has been obtained than that they left off in a stone of light colour. A brine spring was found at about 170 yards deep, which was the only water met with.

"At present, the water, which is pumped up from a depth of 60 yards by iron pipes, and conveyed by pipes of the same material to a reservoir for distribution, becomes charged with the oxyde of that metal, which it possesses not in its natural state. The marble slabs in the bath are stained with the brown marks of the same." *

7 8

1. - "

103

Feet.

Ft.

WOODHALL.

Water overflowed when the shaft was abandoned.

Putting together this information with that above given, Mr. Jukes-Browne believes this boring to have gone through the following beds, and to have terminated in a sandstone belonging to the "A. armatus zone" of the Lower Lias :—

| | Thickness. | Depth. |
|---------------------------------------------|------------|---------|
| | Ft. in. | Ft. in. |
| Gravel and Boulder Clay | 10 0 | 10 0 |
| Kimeridge, Corallian, and Oxford Clays - | 350 0 | 360 0 |
| Kellaways Beds, Cornbrash, Great Oolite | | |
| Clay and Limestone, Upper Estuarine | | |
| Series | 140 0 | 500 0 |
| Lincolnshire Limestone and Northampton | | |
| Sands | 140 0 | 640 0 |
| Lias (Upper, Middle, and part of the Lower) | 380 0 | 1,020 0 |

The spring of saline water issues at a depth of 530 feet, and would, therefore, appear to be in the Inferior Oolite. The shaft is lined with brickwork to this depth.

Mr. Teague, who descended the well in March, 1884, stated to Mr. Cameron that the water stands naturally at 50 feet from the surface, and at 330 feet from the surface when the pump is at work. Pumping carried on for $26\frac{1}{2}$ minutes yielded 640 gallons, lowering the water from 50 to $52\frac{1}{2}$ feet from the surface. The present machinery is capable of raising 1,000 gallons per hour, but is inadequate to drain the well.

10.

ANALYSES OF WATERS.

The water-bearing strata are for the most part calcareous, and the springs and ordinary well-waters of the county contain in solution from about 12 to 30 grains of mineral matter per gallon, chiefly calcium carbonate. The Lias waters, as a rule, contain a larger amount of mineral constituents than the waters of the Oolites or Chalk, while among the Oolites the waters of the Kellaways Beds are often impregnated with an excess of mineral matter.

The character of the constituents depends naturally on the rocks traversed by the waters; and the Lias and Oolites, and some of the Cretaceous rocks and their included fossils, yield not only calcium carbonate, small quantities of magnesium and sodium carbonate, and sodium chloride, but also calcium sulphate and ferruginous compounds derived from the selenite, ironstone and pyrites that are conspicuously present in some of the strata. Sodium chloride is derived also from rain-water through the influence of strong winds from the sea carrying spray and foam.

Ordinary chalybeate springs are not uncommon along the outcrop of the ferruginous strata, but it is only here and there that they have ever risen to the dignity of a Spa, and then, as a rule, but temporarily.

The more strongly saline waters are usually deep-seated, and they may owe their constituents to the saliferous Triassic strata, or in some cases possibly in part to the percolation of sea-water. In all questions of this sort the geological structure and proximity to sea have not only to be considered, but, as Mr. W. W. Fisher points out, also the chemical argument.*

In some cases where the salinity of the water has been due to the damming up of underground waters, so that the ingredients have become concentrated, the pumping of the water may be attended by gradually lessening salinity. Waters must, in many cases, travel long distances underground, and it is likely that the argillaceous strata are less impervious at a depth than at the surface. Records of borings show that clays which are soft and absolutely impervious at the surface, may be hard and jointed shales below ground—the joints or fault planes affording facilities for the passage of water.

On this subject Dr. H. F. Parsons contributes the following notes:

"The water obtained from the Lower Oolite Series (Lincolnshire Linestone) is sometimes of a mineral character, especially where obtained by deep borings at a distance from the outcrop. Thus the water from a public well at Heckington, 400 feet deep, commencing in the Oxford Clay, contains per gallon 128 grains of mineral

* "On the Salinity of Waters from the Oolites," Analyst, Feb., 1904.

matter, the chlorine being 58.5 grains (=96.5 grains of common salt), while the hardness is only 3.6° . A somewhat similar water from Catley is, or used to be, bottled in an aerated state and sold for use as a table-beverage, like Apollinaris or Seltzer water, being, I believe, the only British example of such a water. (See pp. 182, 201).

"The water from a deep boring at Belmisthorpe near Stamford is of a different mineral character, it contains per gallon 107 grains of ε olids, but only 4.7 of chlorine and has 47° of hardness.

"The mineral character of the water obtained from the Lincolnshire Limestone varies according to the distance from the outcrop, the chlorine and total solids increasing with the distance, while the hardness diminishes, as shown in the following table in which the wells are arranged in order from N.W. to S.E.

| Place. M | liles from outerop. | Depth ft. | Total solids. | Chlorine. | Hardness. |

grs. per gallon.

"A series in a different direction, but showing similar results, is given by Mr. H. Preston. (See Table, p. 198.)

"Water of a similar character (*i.e.*, containing much chloride of sodium, often also carbonate of soda), and of a but slight degree of hardness, is obtained in other places from calcareous strata covered by impermeable beds and at a distance from the outcrop, *e.g.*, in S.E. Essex from the Chalk under the Tertiary strata, and in Northamptonshire from the Marlstone under the Upper Lias and Oolite clays. But though one can understand how the water in traversing a great thickness of strata gets charged with mineral matters dissolved out of them, it is not so easy to understand how it gets rid of the carbonate and sulphate of lime. Does this crystallize out as calcite in the interstices of the rocks? Waters of this class appear to have been imprisoned in the strata for long periods of time, and hence in such a case one may doubt the permanence of the supply if much drawn upon by pumping.

"The water obtained from the New Red Sandstone beds near the N. border of Lincolnshire, especially where these beds are covered with clay and peat, and at some distance from the outcrop, contains iron in solution in the state of ferrous carbonate, and often sulphuretted hydrogen, which give it an unpleasant smell and chalybeate taste. On exposure to the air this iron is precipitated as hydrated ferric oxide, and the water, though it loses its taste and smell, becomes turbid with an unsightly brown sediment. Such water, though it may be free from sewage-pollution, is distasteful, so that more palatable water from more dangerous sources is apt

7696.

to be preferred. The iron may, however, be removed by a process of aeration and sedimentation or filtering, or by Clark's softening process. The water from the Red Sandstone in this part of the country is usually hard; much of the hardness being due to magnesia probably derived from débris of the Magnesian Limestone.

"The water obtained by bored wells from the sand and grave beds (?Pleistocene), below the laminated clay, is apt to be of similar character. (See analysis of water from public well at Luddington, p. 207.)

"The water from shallow wells above the clay is commonly polluted with sewage, but the considerable amount of organic matter which it contains is probably derived in part from vegetable remains in the soil; and it also contains rather large amounts of chlorine which may be derived from sea-salt remaining in the beds of estuarine origin. See analyses of waters from well at Eastoft and Garthorpe, pp. 202, 203." H. F. P.

It is noteworthy that the amount of mineral matter in solution in springs is liable to variation at different times.

Dr. Thresh remarks that "The total amount of saline matter permissible in a drinking water depends in a great measure upon the nature of the salts. No hard and fast line can be drawn, but the best waters rarely contain more than 20 grains of mineral matter per gallon. When 100 grains is reached the water becomes rather of the character of a 'mineral' than a 'potable' water."

In some well waters near to the sea-coast or to estuaries, a considerable amount of sodium chloride may be met with, but if the water contains not more than about 50 grains per gallon "it appears to be quite harmless."*

Hardness is due to the presence of salts of lime and magnesia. That known as temporary hardness is produced by carbonates of lime and magnesia, and chiefly by carbonate of lime. It is removable by boiling the water. Permanent hardness is caused by the sulphates of lime and magnesia.

Both sources of hardness are removable by sundry softening processes, but those applied to the permanent hardness are the more expensive.[†]

In the Sixth Report of the Rivers Pollution Commission (p. 21), "a sample containing 1 lb. of carbonate of lime or its equivalent of other hardening salts in 100,000 lbs. is said to have one degree of hardness. Each degree of hardness indicates the destruction and waste of 12 lbs of the best hard soap by 100,000 lbs., or 10,000 gallons of the water, when used for washing." In Clark's Table of Hardness each degree of hardness is equal to one grain of carbonate of lime per gallon. One grain of carbonate of magnesia is equal to about $1\frac{3}{4}$ grains of carbonate of lime. A soft water has less than 6° of hardness.

The scale of hardness used by the Rivers Pollution Commission can be transformed into degrees of hardness on Clark's scale by multiplying the number by seven and then moving the decimal point one place to the left. (op. cit., p. 29).

| | | | | | | | | | | |

The above figures show that the water is saturated with mineral salts, mainly sulphate of lime. These give to the water a nauseous and bitter taste, and absolutely prevent its use for household purposes.

Organically also the water is not pure, although, as the well is shallow and new, the organic pollution could probably be prevented.

As the the water is evidently derived from a soil largely composed of sulphate of lime (Gypsum) it will, in my opinion, be impossible to obtain drinkable water from it unless the strata yielding the lime can be penetrated.

OTTO HEHNER.

April 12th, 1893.

2. Water from subsoil drains in loamy clay over Lias.

100.000 parts of the sample were found to contain-

| - 0 | 0,000 parts | OT ATTO | Samp | 10 1 | | that the | 00 00 | ALL COULTE | | | | |

GRANTHAM-HORNCASTLE.

Heckington.

Analyses by Dr. Alfred Ashby. 1892.

The results of the analyses are expressed in parts per 100,000.

| | - | | | - | | - | | |
|------------------------|------|--------|---|---|---|---|----------------|--------|
| Chlorine - | | | | | | - | 83.80 | 82.70 |
| Equal to common | salt | - | | - | - | - | 138.09 | 136.28 |
| Nitrous acid - | | | | | | - | 0.00 | |
| Nitric acid (N_2O_5) | - | | - | - | - | - | 0.12 | |
| Phosphoric acid | | | | | | - | very faint tra | ce |
| Sulphuric acid | | | | | | | traces | |
| Total solids dried at | (115 | 5° C.) | - | - | - | - | 181.64 | 180.96 |
| Free ammonia | - | - | - | - | - | - | $\cdot 1220$ | · 0996 |
| Albuminoid ammoni | a | - | - | - | - | - | ·0044 | ·0097 |
| Lead and copper | - | - | - | - | - | - | absent. | |
| Total hardness | - | - | - | | | - | 3.64 | |
| Permanent hardness | | - | - | - | - | - | 1.74 | |
| Temporary hardness | | - | ~ | - | | - | 1.90 | |

The analyses show that this is a very pure and soft water, but that the saline matter (equal to 127 grains per gallon) is very high, and gives it a brackish flavour.

On this account it is not fitted for a domestic supply.

Hemswell.

North of village. Chalybeate spring from Northampton Beds.

Horncastle.

1. Water (for boiler-purposes) received from Horncastle Rural District Council, 6th June, 1896.

Analysis by Mr. J. Muter, 18th June, 1896.

| 0.1. | | | | | | ٤ | grains | per gallon. |
|-------------------------|---|---|---|---|---|---|--------|---------------|
| Silica | | - | - | | - | - | - | • 56 |
| Carbonate of lime | - | - | | - | | - | - | •7 |
| Sulphate of lime - | - | - | - | | - | - | - | $928 \cdot 2$ |
| Carbonate of magnesia | - | - | - | - | - | - | - | 1.4 |
| | | | | | | | | |
| Total incrusting solids | - | - | - | - | | - | - | $95 \cdot 48$ |
| Non-incrusting solids | - | - | - | - | - | - | - | 385.42 |
| | | | | | | | | |

Total solids - - 480.9This water is unfit for use in a steam-boiler as, it contains far too much saline matter.

From well at sewage-farm, at the depth of 40 feet. Shaft, 60 feet; bored, 30 feet. Fair supply.

2. Analysis of Water Company's water by the Clinical Research Association, London.

Communicated by the Local Government Board.

| Colour in 2 ft. tube | | | | | | sh green amount |
|-------------------------------------|---|---|---|---|---|--------------------|
| * | | | 2 | | | ns per gallon |
| Total Solid Residue (dried at 120°) | | - | - | - | - | 17.15 |
| Combined Chlorine | - | - | - | | - | 1.30 |
| Expressed as Common Salt | - | | 1 | - | - | 2.14 |
| Nitrogen as Nitrates | - | - | | - | - | 0.23 |
| Nitritos | | | - | 2 | Ŧ | absent |

ANALYSES.

2. Analysis of Water Company's water by the Clinical Research Association, London—continued.

| | | | | | | | | grain | ns per gallon. |
|------------------|---------|--------|-------|-------|-------|-----|---|-------|----------------|
| Saline Ammonia | - | | - | - | - | - | - | tra | ces only |
| Albuminoid Amn | nonia | - | - | - | - | · - | - | - | 0.00049 |
| Oxygen required | to oxic | lise t | the O | rgani | c mat | ter | - | - | 0.0130 |
| Hardness (in deg | ree) | - | - | - | - | - | - | - | 13·4° |
| Lead or Copper | - | - | - | - | - | - | - | - | absent |

The above analytical results are satisfactory, and the water may be quite safely used for drinking purposes.

Kingerby Spa.

South of village, by Kingerby Wood.

Chalybeate spring, which seems to issue from the base of a lenticular bed of sand which here intervenes between the Boulder Clay and the Oxfordian. (A. J. Jukes-Browne, in *Geol. Lincoln*, p. 135).

Leadenham.

Communicated by Mr. H. Preston.

Water from the Lower Lias; band of ironstone belonging to zone of *Ammonites semicostatus*. There is evidence that this band thins out eastwards, in which case the water would be retained in a stagnant condition.

| | | | | | | | | | | |

This is a good and pure water. It is hard, but that is a character belonging to limestone waters. A large portion of the hardness may be removed by boiling the water for about half an hour.

ALFRED ASHBY.

Luddington.

Water from public well sunk by Goole Rural Sanitary Authority near site of old river Don.

Well 24 ft. deep, made watertight with large stoneware pipes as far down as clay bed, and bored to depth of 57 ft. from surface, through the elay into brown sand with some pebbles. Water clear when first drawn, with strong chalybeate taste and smell; on standing it became very turbid, but free from taste or smell.

| Total " | - | - | - | | - | - | - | - | 40·ŏ |
| Lead and Copper | - | | | - | - | - | - | - a | bsent |

This water is remarkably pure, containing as it does only a very minute quantity of organic matter. It is, however, very hard, the total solid being high, and unfortunately the permanent hardness is very great, constituting about half of the total hardness.

The hardness could be reduced to nearly one-half by the use of lime, or to a still greater extent in other ways.

ALFRED ASHBY,

March 5th, 1898.

POTTER HANWORTH-ROXBY.

Roxby-cum-Risby.

Communicated by Mr. H. Preston.

1.-Risby Warren. Lincolnshire Limestone water.

Analysis made by Professor J. A. Wanklyn, October 17th, 1894. Bore Water.

| | | | | | | | grai | ins _l | per gallon. |
|---------------------|------|-------|------|----|--------|-----|--------|------------------|-------------|
| Carbonate of lime | - | - | - | | - | - | | - 1 | 16.0 |

This is a palatable and exceedingly pure water without any suspicion of sewage-contamination. It is hard, but that is a character natural to limestone waters, whilst it is much less so than the polluted surface well waters of the district.

ALFRED ASHBY.

Scredington.

Analysis of water from boring, 219 feet through Oxford Clay into Lower Oolites. (See p. 152). Jesse Clare, 22nd April, 1897.

Communicated by the Local Government Board.

Results expressed in parts of 100,000.

F 1

From these analyses it appears that the water although organically pure, is loaded with saline constitutents, and that it is unfit for a town's supply. 7696. O 2

B. Analyses by Dr. J. Muter, November, 1901.

1. Analysis for Mineral Constituents

| | | | | | | | | grains per gallon. |
|--------------------|---|---|---|---|---|---|---|--------------------|
| Calcium sulphate | - | - | - | - | - | - | - | - 146.72 |
| Calcium carbonate | - | - | - | - | - | - | - | - 2.45 |

| | | | | | | | | | |

The analysis shows that this water is extremely pure and without suspicion of pollution of any description. Like all limestone-waters it is hard, but it is much less so than the water obtained from the polluted surface-wells of the district. It is well adapted for a public supply.

Uffington.

Analysis of water from boring 219 feet deep in Lower Oolites, received from Mr. F. Dickinson, Chemist, St. Mary's Street, Stamford.

Communicated by the Local Government Board.

| Total solid matter - | - | - | - | Grains per gallon | - 30 |
|--------------------------|--------|------|---|-------------------|---------------|
| Free ammonia - | - | - | - | Parts per million | - none |
| Albuminoid ammonia- | - | - | - | 31 33 39 | slight traces |
| Nitrogen as nitrites and | nitrat | tes- | - | Grains per gallon | slight traces |
| Chlorine | - | - | - | 22 22 22 | - 2.0 |
| Degrees of hardness - | - | - | - | | - 23.5 |
| Metals, Lead or Copper | - | - | - | | - none |

There being an entire absence of free ammonia and only slight traces of nitrogen and albuminoid ammonia with a small amount of chlorine present, in our opinion the water is of average purity and one well suited for drinking and other purposes.

JOHN RICHARDSON & Co., Leicester, Limited.

H. N. B. RICHARDSON, B.A., F.C.S., Director.

November 2nd, 1898.

Walcot Spa.

N.W. of Billinghay. 256 grains of mineral matter per gallon. (Dr. T. Short).

Woodhall Spa.

From an account by Dr. Robert Barnes in "The Climates and Baths of Great Britain." vol. i. 1895, p. 575.

The well, according to Mr. R. B. Latham, yields 1,100 gallons per hour "After three week's cessation of pumping, the water stood at 122 feet below the surface, and *much below the level of the sea*. He also inferred, judging from the temperature of the water, 56°F. at a depth of 140 feet from the surface, that there is every probability that the water comes from the depth indicated, namely, about 500 feet. It is not at all unlikely," adds Mr. Latham, "that the spring has a direct connection with the sea."

The following is the result of an analysis made by Sir E. Frankland in 1891

"The water was collected on the 22nd of May last. It was very turbid when drawn from the well, but became clear on standing for about ten days, the deposited reddish matter consisting almost entirely of hydrated peroxide of iron. The sp. gr. of the clear water at 50° F. was 1.0165. The water tested soon after collection contained neither free iodine nor arsenic.

100,000 parts of the clear water left, on evaporation and drying at 340° F. a solid residue of $2262 \cdot 4$ parts, from which the following constituents were obtained :

| | | | | | | | | | | | Parts. |
|---|------------|-------------------|--------|------------------|-----|---|---|---|---|---|-----------------|
| | Soda (Na | a ₂ O) | - | - | - | - | | - | ~ | - | $1037 \cdot 0$ |

| Free iodine | - | - | - | - | ·20 | ·28 |
| Iodine (as iodates) - | - | - | - | - | ·20 | •28 |
| lodine (as iodides) - | - | - | | | • 40 | · 56 |
| Bromine (as bromides) | - | - | | - 1 | 3.40 | 4.85 |
| Peroxide of iron - | - | - | - | - | traces | traces |

A previous analysis by Professor Wanklyn, made in December, 1886, gave the following result :---

Dr. Barnes, after referring to the differences in the analyses, observes that "the question arises whether the supply of iodides and bromides is constant and uniform." In an analysis by Frankland in 1874 the amount of iodine in 100,000 parts was \cdot 880, and of bromine $6\cdot$ 280; in an analysis by Messrs Wright & Burton in 1883, the iodine was \cdot 5216 and the bromine $4\cdot$ 9729.*

It is interesting to find that, not far from the church at Woodhall, at a depth of 33 feet, "a spring of salt water was tapped, resembling that of Woodhall Spa, but it gradually became less salt, and was finally replaced by a supply of fresh water."[†]

ANALYSES OF KIMERIDGE CLAY FROM BENNIWORTH.

Communicated by Mr. J. Stuart Bogg.

The following analyses of cores and samples from the Benniworth boring (see p. 48) were made by Mr. F. W. Richardson, F.I.C., F.C.S., City Analyst for Bradford :---

1. Sample of dark clay, from depth of 78 ft. 2 in., received Mar. 4th, 1904.

| | | | | | | Moist sample. | Dry sample (burnt.) |

2. Sample of clay bluish, with fossils, from depth of 97 ft. 2 in. Received Mar. 16th, 1904.

This is much better than the previous sample, as it contains only a small quantity of lime carbonate, and consists of clay to the extent of 96 per cent.

3. Two samples of shale. Received April 28th, 1904.

This is a very poor yield of ammonia, as one ton of an average shale would yield ammonia equal to about 25 lbs. of sulphate of ammonia.

The yield of oils is fairly satisfactory when we consider the fact that only a small quantity was available for distillation. On a larger scale the amount of oils obtained would be greater.

4. Two samples of clay. No. 1 sample was from a 13 in. seam at the depth of 306 ft., and No. 2 from a 12 in. seam at the depth of 309_4^3 ft. Received April 29th, 1904.

2. REPORTS OF MEDICAL INSPECTORS OF PRIVY COUNCIL AND LOCAL GOVERN-MENT BOARD ON LINCOLNSHIRE.

(Communicated by Dr. H. F. Parsons.)

In the Annual Reports of the Medical Officer (Sir J. Simon) to the Privy Council, reports by Medical Inspectors on the following Lincolnshire localities were referred to :-

1864. BRISTOWE, DR. On Fever at Grantham. 1868. THORNE, DR. R. THORNE. On Epidemic of typhoid fever at Winterton.

| 1870. | RADCLIFFE, NETTEN. | Fever at Ingham. |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| | | Fever at Scothern. |
| | Bernard and a second second research and a second s | Fever at Stamford. |

Of these reports only extracts or abstracts were published. All had to do with the prevalence of typhoid fever, and in each case polluted water is given as one of the causes.

- 1880. PARSONS, Dr. H. F. Report on the Sanitary Condition of the Sutton Bridge Urban Sanitary District.
- 1881. PARSONS, Dr. H. F. Report on the Sanitary Condition of Great Grimsby.
- 1882. PARSONS, Dr. H. F. Report on an Outbreak of Diphtheria at Gedney Drove End, and on Enteric Fever at Whaplode Drove, in the Holbeach Rural Sanitary District.

1833. PARSONS, Dr. H. F. Report on the prevalence of Scarlet Fever and Diphtheria in the Thorne Registration District, and on the general Sanitary condition of the Districts comprised therein. (Refers to Crowle and the Isle of Axholme.)

1885. GRESSWELL, Dr. D. ASTLEY. Report on two Outbreaks of Enterie Fever in the Rural Sanitary District of Lincoln.

-Report on the Prevalence of Diphtheria in the Rural Sanitary District of Glanford Brigg.

-SPEAR, JOHN. Report on the prevalence of Diphtheria in the Spilsby Rural Sanitary District.

- 1888. PAGE, Dr. D. Report on the Sanitary State of the adjoining Urban Sanitary Districts of Clee-with-Weelsby and Great Grimsby, with reference to the Prevalence of Enteric Fever there.
- 1890. PARSONS, Dr. H. F. Report on an Epidemic of Pneumonia at Scotter, Lincolnshire, and in the neighbouring places.

-Report on the Water Supply of Barrowby, in the Grantham Rural Sanitary District.

- 1893. Low, Dr. R. BRUCE. Report on the circumstances of the River Trent in Lincolnshire and part of Nottinghamshire, with special reference to the Water Supplies of Populations resident on or near the banks of the river, and to the occurrence amongst those Populations of Enteric Fever.
- Report on Cholera in 1893 in Grimsby and in 1894. REECE, Dr. R. J. Cleethorpes with Thrunscoe. (In Report of Medical Officer, Loc. Gov. Board, on Cholera in England in 1893.)

- 1895. Evans, E. Report upon an Outbreak of Diphtheria in the town of Holbeach.
- 1898. WHEATON, Dr. S. W. Report on outbreaks of Diphtheria at Marston, Hougham and Long Bennington, in the Claypole Rural District.
- 1899. MAIR, Dr. L. W. DARRA. Report upon the Sanitary Circumstances and Administration of the Urban District of Gainsborough, with special reference to the prevalence of Fever therein.

-----Low, Dr. R. B. Report on an Outbreak of "Fever" in the village of South Witham, in the Grantham Rural District, South Lincolnshire.

- 1901. COPEMAN, Dr. S. M. Report on the General Sanitary Circumstances and Administration of the Borough of Boston.
